- At those times when the maximum discharge capacity of the outlet works limits the ability to pass inflows, the excess inflow volume will be retained in storage.

## **5 Seasonal base flow management strategy**

### **5.1 Theodore Weir seasonal base flow management strategy**

A seasonal base flow equal to the inflow to Theodore Weir must pass Theodore Weir if:

- Inflows to the weir are between 60 ML/day and 100 ML/day;
- The water level in the weir is above EL 133.0 m AHD (4,200 ML); and
- The upper Dawson sub-scheme first post-winter flow management strategy is not in effect.

A seasonal base flow of 100 ML/day must pass Theodore Weir if:

- Inflows to the weir are greater than 100 ML/day;
- The water level in the weir is above EL 133.0 m AHD (4,200 ML); and
- The upper Dawson sub-scheme first post-winter flow management strategy is not in effect.

Seasonal base flow passed through Theodore Weir is in addition to any release required for supply between Theodore Weir and the Moura Weir pond.

For the purpose of implementing this strategy:

- The volume passed over a 48-hour period must be within plus 20% and minus 20% of the volume required to be passed under the strategy;
- The commencement and cessation of any release required under this strategy may be delayed by up to 48 hours; and
- Inflows to the weir do not include any water which was released from Gylanda Weir intended to maintain the level in Theodore Weir at its nominal operating level or to supply users between Gylanda Weir and the Theodore Weir pond.

### **5.2 Moura Weir seasonal base flow management strategy**

A seasonal base flow equal to the inflow to Moura Weir must pass Moura Weir if:

- Inflows to the weir are between 70 ML/day and 110 ML/day;
- The water level in the weir is above EL 102.8 m AHD (4,500 ML); and
- The upper Dawson sub-scheme first post-winter flow management strategy is not in effect.

A seasonal base flow of 110 ML/day must pass Moura Weir if:

- Inflows to the weir are greater than 110 ML/day;
- The water level in the weir is above EL 102.8 m AHD (4,500 ML); and
- The upper Dawson sub-scheme first post-winter flow management strategy is not in effect.

Seasonal base flow passed through Moura Weir is in addition to any release required for supply in the reach between Moura Weir and the Neville Hewitt Weir pond.

For the purpose of implementing this strategy:

- The volume passed over a 48-hour period must be within plus 20% and minus 20% of the volume required to be passed under the strategy;

- The commencement and cessation of any release required under this strategy may be delayed by up to 48 hours; and
- Inflows to the weir do not include any water which was released from Theodore Weir intended to maintain the level in Moura Weir at its nominal operating level or to supply users between Theodore Weir and the Moura Weir pond.

### **5.3 Neville Hewitt Weir seasonal base flow management strategy**

A seasonal base flow equal to the inflow to Neville Hewitt Weir must pass Neville Hewitt Weir if:

- Inflows to the weir are between 70 ML/day and 110 ML/day;
- The water level in the weir is above EL 77.0 m AHD (4,000 ML); and
- The lower Dawson sub-scheme first post-winter flow management strategy is not in effect.

A seasonal base flow of 110 ML/day must pass Neville Hewitt Weir if:

- Inflows to the weir are greater than 110 ML/day;
- The water level in the weir is above EL 77.0 m AHD (4,000 ML); and
- The lower Dawson sub-scheme first post-winter flow management strategy is not in effect.

Seasonal base flow passed through Neville Hewitt Weir is in addition to any release required for supply between Neville Hewitt Weir and the downstream limit of the Boolburra waterhole.

For the purpose of implementing this strategy:

- The volume passed over a 48-hour period must be within plus 20% and minus 20% of the volume required to be passed under the strategy;
- The commencement and cessation of any release required under this strategy may be delayed by up to 48 hours; and
- Inflows to the weir do not include any water which was released from Moura Weir intended to supply users between Moura Weir and the Neville Hewitt Weir pond.

## **6 Fishway management strategy**

### **6.1 Moura Weir**

The ROL holder is authorised to operate the Moura Weir fishway when:

- Flows passing the weir are greater than 80 ML/day; and
- The weir storage level is between EL 102.75 m AHD and 105.47 m AHD.

The ROL holder may operate the fishway at other times, provided the releases from the weir are not more than that required to:

- Supply water;
- Meet the requirements of the upper Dawson sub-scheme first post-winter flow management strategy; and
- Meet the requirements of the seasonal base flow management rules.

## 6.2 Neville Hewitt Weir

The ROL holder is authorised to operate the Neville Hewitt Weir fishlock when:

- Flows passing the weir are greater than 80 ML/day; and
- The weir storage level is between EL 78.3 m AHD and 81.1 m AHD.

The ROL holder may operate the fishlock at other times, provided the releases from the weir are not more than that required to:

- Supply water;
- Meet the requirements of the lower Dawson sub-scheme first post-winter flow management strategy; and
- Meet the requirements of the seasonal base flow management strategy.

## 7 Quality of water released from storages

Where a storage incorporates a multi-level outlet, the ROL holder must draw water from the level that optimises the quality of the water released (for example, dissolved oxygen concentration and the temperature in the release water optimised), to minimise the impact on the downstream water quality. If this level does not provide enough capacity for the required release, other levels must be used to give the required discharge.

## 8 Use of watercourses for distribution of water

The ROL holder may use the following watercourses for the purposes of distribution of water:

- The Dawson River from the upstream limit of Glebe Weir to the downstream limit of the Boolburra waterhole; and
- Sections of tributaries of the Dawson River that contain water from natural waterholes and infrastructure within the above section of the Dawson River.

The ROL holder must not divert water to any watercourse other than those given above for distribution of water.

## 9 Riparian stock and domestic use

Under Section 20(3) of the Water Act, an owner of land adjoining a watercourse, lake or spring may take water for domestic purposes and watering stock that would be normally depastured on the land without a water entitlement. In this section this is referred to as 'riparian entitlement water'.

This means that riparian entitlement water might also be taken through the same metered water facilities as supplemented water and some users might desire appropriate allowances be made for their riparian entitlement water use. The historical arrangements for accounting for individual riparian use taken through metered facilities will not apply following commencement of the ROP.

### 9.1 Rules for adjusting metered use for riparian entitlement water use

This section provides arrangements to allow adjustments for riparian entitlement water metered use.

The ROL holder must enter into an arrangement with any water user who requests metered

use adjustments for riparian entitlement water use taken through a metered facility. The ROL holder must supply details of the arrangements with each individual user to the chief executive within 5 business days of an agreement.

An arrangement must comply with the departmental guidelines for this purpose.

If the ROL holder and a water user are unable to reach agreement on an arrangement, the chief executive will decide the arrangement that will apply in that particular instance.

# Attachment 4.1F

## Dawson Valley Water Supply Scheme

### Water sharing rules

This attachment provides water sharing rules for:

- Announced allocations;
- Critical water supply;
- Transfer of water between water years; and
- Seasonal water assignments.

There are three types of water allocation supplied to water users in the Dawson Valley Water Supply Scheme, namely medium, medium A and high priority water allocations. The water sharing rules specify the way the water resources of the Dawson Valley Water Supply Scheme will be shared between each of the water allocation priority groups.

For the purposes of this attachment, an interim water allocation must be managed as if it is a water allocation.

#### **1 Announced allocation rules**

The announced allocation percentage is the percentage of the water allocation nominal volume that may be supplied during the water year.

The Resource Operations Licence (ROL) holder is required to calculate announced allocation percentages for each priority group through the use of formulas and associated parameters. Details for each parameter used are specified in Section 5.

The amount of water that can be apportioned to each of the priority groups at any given time is determined by taking into account a number of factors, including:

- The time of year an assessment is made;
- The amount of water used in the current water year up to the date of the assessment;
- The amount of water stored in the storages;
- Allowance for evaporative and seepage losses from storages;
- Allowance for future inflows and the probability of those inflows occurring at particular times in the water year;
- Allowance for the requirements of high priority water allocation for the first four months of the next water year;
- Allowance for transmission and operational losses along the river; and
- The net amount of the water allocation volume moved into the current water year from the previous water year.

The values for these factors applied in the announced allocation formula seek to maximise the availability of medium and medium A priority water allocation and secure the reliability for high priority water allocations as determined by testing in the department's hydrologic model (IQQM) over the long-term historical period. Importantly the values given for these factors should not be taken out of the context of their purpose as part of the overall package used to

determine the announced allocation. For example, the values for some of the factors vary depending on the probability of natural inflows which in effect reduce the need for future provisions associated with losses at certain times of the year.

The announced allocation formula provides for announced allocation differential of up to 20% for medium A priority water allocations over medium priority water allocations in the upper Dawson sub-scheme. This is consistent with arrangements previously in place for supplies from the channel systems in the Dawson scheme.

### **1.1 General rules for announced allocations**

The water year for the Dawson Valley Water Supply Scheme is from 1 October to 30 September in the following year.

Separate assessment of announced allocation percentage must be made for each priority group in each sub-scheme.

The initial announced allocation percentage for a water year must be announced within 2 weeks after the start of that water year.

The ROL holder may announce an interim announced allocation at any time during a water year. An interim announced allocation percentage must not be greater than the percentage that would be calculated using the formulas in Section 1.2. An interim announced allocation has effect as if it was an announced allocation calculated using the formulas in Section 1.2.

The ROL holder must announce an interim announced allocation immediately prior to the commencement of a water year. The basis/criteria for the determination of the interim announced allocation for the start of the water year must take into account water user requirements, and be made available to water users.

Announced allocation percentages must not be reduced during a water year.

Announced allocation percentages must not be greater than 100%.

Announced allocation percentages must be rounded to the nearest 1%.

Announced allocation percentages must be reviewed, and revised percentages announced within 2 weeks after a major inflow occurs. A major inflow is defined as one that would result in:

- For times when the announced allocation is less than 10% prior to the inflow:
  - The announced allocation percentage increasing by 2% or more;
- For times when the announced allocation is more than 10% prior to the inflow:
  - The announced allocation percentage increasing to 100%; or
  - The announced allocation percentage increasing by 5% or more.

If the announced allocation percentage is less than 100%, the announced allocation percentage should be reviewed at intervals not greater than 3 months.

The ROL holder should advise water users of forecast announced allocations, including details of the parameters used in determining the forecast values. The criteria for forecasting announced allocations, including the timing, frequency and level of accuracy must take into

account water user requirements, and be made available to water users.

## 1.2 Calculation of announced allocation percentages

### 1.2.1 Medium and medium A priority water allocations

#### 1.2.1(a) Upper sub-scheme

The initial announced allocation and any revised announced allocations for medium priority water allocations (AAm) and for medium A priority water allocations (AAma) must be determined from the following relationships.

$$(AAm * MPA) + (AAma * MAPA) = (UV + IN \quad HPA \quad RE \quad TOL + USE \quad VIWY) * 100$$

Where:

If AAma ≤ 20%, AAm = 0%

If AAma > 20%, AAm = AAma-20%

If AAm > 80%, AAma = 100%

The parameters used in these relationships are defined in Section 5.

#### 1.2.1(b) Lower sub-scheme

The announced allocation percentage for medium priority water allocations in the lower sub-scheme must be determined from the following relationship.

$$AAm * MPA = (UV + IN \quad HPA \quad RE \quad TOL + USE \quad VIWY) * 100$$

The parameters used in this relationship are defined in Section 5.

## 1.2.2 High priority water allocations

The announced allocation percentage for high priority water allocations in a sub-scheme (AAh) must be 100% if the announced allocation percentage determined for both medium and medium A priority water allocations in that sub-scheme is greater than zero.

If the announced allocation percentage for medium and medium A priority water allocations in a sub-scheme is zero, the amount of water that may be taken by high priority water allocations in that sub-scheme may be subject to the critical water supply water sharing rules in Section 2.2.

## 2 Critical water supply water sharing rules

### 2.1 Critical water supply water sharing rules for 1 July to 30 September

The announced allocation arrangements preferred by irrigators and adopted for this ROP is an aggressive approach whereby the amount of water allocated in the early part of the water year is more than the amount available in storage at that time to assure supply of all allocated water throughout the water year. Essentially this means that there is an inherent dependence on wet season inflows to satisfy these allocations established prior to the wet season.

To account for the risks associated with the aggressive announced allocation approach, these critical water supply rules aim to provide a safety net for supplies for essential needs in the event that all the allocated water cannot be supplied. Circumstances when these rules might need to be applied include for example, the failure of a wet season to significantly replenish storages or due to a marked overall shift in the current irrigation demand pattern towards the latter part of the water year.

Under these rules, the available supplies are shared between water users proportionally to the volume of unused entitlement, after high priority water needs for the start of the next water year, and essential water needs for the current water year, such as drinking water, are addressed.

### **2.1.1 Activation of the rules**

For each sub-scheme, activation of these critical water supply water sharing rules must be decided by the ROL holder as soon as practicable after 1 July on the basis of the third quarter meter readings and usage assessments as follows:

- The ROL holder must assess the amount of available supply for the remainder of the water year after making the normal provisions under the announced allocation rules for high priority supply into the next water year and losses.
- The ROL holder must assess the amount of unused entitlement.
- If the unused entitlement is more than 5% greater than the available supply, the ROL holder must activate the rules given in Section 2.1.3.

### **2.1.2 End of the rules**

The ROL holder must end the critical water sharing rules activated under Section 2.1.1 in a sub-scheme and resume normal announced allocation procedures:

- If the announced allocation for medium and Medium A priority allocation increases; or
- At the end of the water year.

An announced allocation increase confirms that the supply availability has been restored to a safe condition for the remainder of the water year.

### 2.1.3 Critical water sharing rules for 1 July to 30 September

If these rules are activated under Section 2.1.1, the ROL holder must discontinue supply under the announced allocation arrangements and re-allocate the available supplies in the sub-scheme as follows:

- (a) Determine the essential water needs (refer to Section 2.1.4) for the remainder of the water year and allocate water in proportion to those needs up to the lesser of:
  - The total amount of available supply; or
  - 10% of the nominal high priority allocation in the sub-scheme; and
- (b) Allocate the remainder of the available supply in proportion to the unused individual entitlements as adjusted for any allocation made under (a) above.

While these rules are active, the ROL holder must regularly review the available supply and the unused entitlement.

If a review results in more than 10% additional water being available for supply than currently allocated under these rules, the ROL holder must proportionally allocate the additional water to the holders of unused entitlements when these rules were activated. Additional allocation should first address any allocation shortfall under (a) above.

An allocation under this section must not exceed an individual's entitlement at the time.

### 2.1.4 Essential water needs

For the purpose of this critical water supply water sharing rule, essential water needs must include that part of a town water supply required for essential services including drinking water and sanitation but excluding lawns and gardens. The ROL holder in conjunction with water allocation holders may establish additional essential purposes.

## 2.2 Critical water supply water sharing rules for high priority water allocations when announced allocation for medium and medium A priority water allocations are zero

The ROL holder may implement restrictions on the supply of high priority water in a sub-scheme provided:

- The announced allocation for both medium and medium A water allocations in the sub-scheme is zero;
- The restrictions are decided by the ROL holder in conjunction with high priority water allocation holders; and
- The objectives of the Water Resource Plan (WRP) are not compromised.

Factors that should be taken into account when deciding whether to implement restrictions, and the nature of those restrictions, include:

- The amount of water available in the system, and its distribution between each of the storages in each sub-scheme;
- The rules for releases of water from storages;
- The amount of high priority water allocation demand and its distribution, both spatially and temporally;
- The likely evaporative, transmission and other operational losses that may be incurred in delivering the water to water allocation holders;
- The circumstances and needs of individual high priority water allocation holders;

- The ability of individual high priority water allocation holders to modify their water demands; and
- The likelihood of further inflows in the short and medium term.

Restrictions that may be imposed may include, but are not limited to:

- An announced allocation, limiting the amount of water that may be supplied to high priority water allocation holders; and
- Limitations on the amount of high priority water allocation that may be supplied to an individual in a specific period (for example, maximum daily diversion rate, maximum weekly diversion rate in a particular month, maximum diversion to a particular date).

### **3 Transfer of water between water years**

The ROL holder may develop and apply scheme practices for carry over and forward draw of water entitlements in accordance with the principles and rules in this section.

#### **3.1 Principles for transfer of water between water years**

The ROL holder must have regard to the following principles in developing and applying scheme practices for carry over and forward draw of water entitlements.

Carry over and forward draw practices must not have an adverse impact on the objectives of the WRP.

Entitlements must not be:

- Carried over from the current water year to any future year other than the next water year; or
- Brought forward from a future water year to the current water year, other than from the next water year.

The volume of an individual water entitlement carried over to the next water year must not exceed the unused portion of the entitlement at the end of the water year. The unused portion of an entitlement must not exceed the amount determined under section 2.1.3, if the critical water supply water sharing rules for 1 July to 30 September applied to the entitlement at the end of the water year.

The volume of individual water allocation brought forward to the current water year must not exceed the announced allocation volume for the allocation at the start of the next water year.

The ROL holder must apply such loss factors to carry over water as necessary to avoid:

- Adverse impacts on other water entitlement holders; and
- Adverse impacts on the objectives of the WRP.

The ROL holder must consider the effects of storage overflow on the volume of carry over.

### **3.2 Rules for transfer of water between water years**

The following rules apply for the transfer of water between water years.

The total volume permitted to be brought forward to a water year for a sub-scheme must not exceed 10% of the total nominal allocation for that sub-scheme.

Forward draw to a water year must not be permitted prior to finalisation of the assessments for the activation of critical water supply water sharing rules for 1 July to 30 September given in Section 2.

The total volume permitted to be carried over to a water year for a sub-scheme must not exceed 10% of the total nominal allocation for that sub-scheme.

Carry over from the current water year to the next water year must not be permitted prior to finalisation of the assessments for the activation of critical water supply water sharing rules for 1 July to 30 September given in Section 2.

The ROL holder must not supply water carried over from the previous water year that was unused:

- At 1 November; or
- For the upper sub-scheme, at the time an overflow of Moura Weir commences; or
- For the lower sub-scheme, at the time an overflow of Neville Hewitt Weir commences.

### **3.3 End of water year minor adjustments**

As an administrative arrangement to account for the timing of the end of water year metered use reading and for the operational convenience of water users, the ROL holder may, in addition to any carry over or forward draw permitted under Section 3.1 and Section 3.2, make minor carry over and forward draw adjustments to entitlements. For an individual, the adjustments must not exceed 2% of the individual entitlement at the end of the water year for which the meter reading applies, or 10 ML whichever is the lesser.

## **4 Seasonal water assignment rules**

Under Section 146B of the Water Act the holder of a water allocation may enter into an arrangement for a seasonal assignment in relation to the allocation. However, the allocation holder may enter into the arrangement only with the consent of the ROL holder. The ROL holder may give consent only if the assignment is allowed under the seasonal water assignment rules in the ROP.

For the Dawson Valley Water Supply scheme, there are few specific rules given in the ROP. For example, volume limits for seasonal assignments within each sub-scheme are not specified. This approach allows the ROL holder greater flexibility to develop scheme practices for seasonal assignment in conjunction with the water users that suit the wide range of difficult supply circumstances specific to this system.

The ROL holder is required to report (refer Section 4.1.1 of Attachment 4.1G) on trends in seasonal assignment and evaluate whether seasonal assignment practices are impacting on supply for individual water users or groups of water users or impacting on the objectives of the WRP.

Chapter 8 of the ROP allows the chief executive to initiate changes to the seasonal assignment rules if considered necessary to protect the objectives of the WRP.

#### 4.1 Principles for seasonal water assignment

The ROL holder must have regard to the following principles in developing scheme practices and for making decisions for consent of seasonal water assignment arrangements.

The effects of an individual seasonal assignment and the cumulative effects of successive or repeated seasonal assignments must not:

- Impact adversely on the WRP objectives;
- Impact adversely on the availability of water to other water users in any part of the scheme; or
- Subject waterholes to an increased potential for environmental harm.

The water under seasonal assignment may only be supplied from within the Dawson Valley Water Supply Scheme area.

#### 4.2 Rules for seasonal water assignment

The following rules apply in developing scheme practices and for making decisions for consent of seasonal water assignment arrangements.

Water supplied under a seasonal water assignment may be used for any purpose.

Seasonal assignment of a water allocation with a specified purpose of ‘distribution loss’ is not permitted.

The net amount of seasonal water assignment between the upper Dawson sub-scheme and the lower Dawson sub-scheme must not exceed the limits given in Table 1.

**Table 1: Permitted net amount of seasonal water assignment between sub-schemes**

Upper Dawson sub scheme to lower Dawson sub-scheme (ML)	Lower Dawson sub-scheme to upper Dawson sub-scheme (ML)
200	0

## 5 Definition of parameters

### **AAM = Announced allocation percentage medium priority**

The percentage of the nominal volume for a medium priority water allocation that may be supplied for the current water year in a sub-scheme.

### **AAMA = Announced allocation percentage medium A priority**

The percentage of the nominal volume for a medium A priority water allocation that may be supplied for the current water year in a sub-scheme.

### **MPA = Medium priority water allocations**

The volume of medium priority water allocations in a sub-scheme.

**MAPA = Medium A priority water allocations**

The volume of medium A priority water allocations in a sub-scheme.

**HPA = High priority allocations**

The volume of high priority water allocations in a sub-scheme.

**USE = Total volume of water taken**

The volume of water taken in a sub-scheme in the current water year up to the time of the assessment of the announced allocation (excluding any water taken in the current water year that had been carried over).

**UV = Useable volume**

UV is determined by summing the useable volume of each of the storages included in the assessment of the announced allocation, as per the following equations:

$$UV = \text{sum}(UV_{\text{storage}})$$

$$UV_{\text{storage}} = CV - DSV - SL$$

$$UV_{\text{storage}} = 0 \text{ if } CV - DSV - SL \text{ is less than zero}$$

Where:

UV<sub>storage</sub> is the useable volume of each storage.

CV is the current volume of the storage.

DSV is the dead storage volume of the storage.

SL is the storage losses.

For the purpose of assessment of the announced allocations, the volumes of Glebe Weir, Gylanda Weir, Theodore Weir, Moura offstream storage, and Moura Weir are included in the calculation for the upper sub-scheme, while the volume of Neville Hewitt Weir is included in the calculation for the lower sub-scheme. The volume of Orange Creek Weir is ignored in the calculation.

**SL = Storage losses**

SL is the projected storage losses from the storages for the remainder of the water year.

The storage loss depths to be used for each storage are given in Table 2. The value next to the current month is multiplied by the current surface area of the storage. The storage loss for each storage is determined and then summed to give the total storage loss.

**Table 2: Projected storage losses for each storage**

Month in which announced allocation is calculated	Upper sub-scheme storage loss (mm)	Lower sub-scheme storage loss (mm)
October	990	990
November	990	990
December	990	990
January	990	990
February	990	990
March	815	815
April	645	645
May	515	515
June	420	420
July	340	340
August	255	255
September	145	145

**IN = Inflow**

IN is the allowance for inflows used in the calculation of the announced allocation. The inflows to be used are given in Table 3. The value which must be used for inflows is the value in the table for the month in which the calculation is undertaken.

**Table 3: Inflow allowances**

Month in which announced allocation is calculated	Upper sub-scheme inflows (ML)	Lower sub-scheme inflows (ML)
October	2,500	700
November	1,555	432
December	1,447	432
January	1,379	47
February	0	0
March	0	0
April	0	0
May	0	0
June	0	0
July	0	0
August	0	0
September	0	0

**RE = Reserve**

RE is the storage volume set aside for supply and associated losses in future water years. The reserve volumes for calculating the announced allocations are given in Table 4. The value for the current month at the time of the calculation is the value used.

**Table 4: Reserve volumes**

Month in which announced allocation is calculated	Upper sub-scheme reserve (ML)	Lower sub-scheme reserve (ML)
October	2,500	700
November	1,555	432
December	1,447	432
January	1,379	47
February	4,000	1,500
March	4,000	1,500
April	4,000	1,500
May	4,000	1,500
June	4,000	1,500
July	4,000	1,500
August	4,000	1,500
September	4,000	1,500

**TOL = Transmission and operational losses**

TOL is an allowance for river transmission and operational losses expected to occur in running the system from the date of the announced allocation assessment to the end of the current water year. TOL varies with the announced allocation for medium priority water allocations.

TOL are calculated using the formula below. Values for TOL1 and TOL2 are given in Tables 5 and 6. TOL1 and TOL2 are to be linearly interpolated for intermediate values of medium priority announced allocation.

**Upper sub-scheme**

$$\text{TOL} = \text{TOL1} * \frac{[\text{MPA} + \text{MAPA} + \text{HPA} - \text{USE}]}{\text{MPA} + \text{MAPA} + \text{HPA}}$$

**Lower sub-scheme**

$$\text{TOL} = \text{TOL2} * \frac{[\text{MPA} + \text{HPA} - \text{USE}]}{(\text{MPA} + \text{HPA})}$$

**Table 5: TOL1 for upper sub-scheme**

Upper sub-scheme transmission and operational loss (ML)				
At 0% AAm	At 10% AAm	At 50% AAm	At 80% AAm	At 100% AAm
250	550	1300	1700	1850

**Table 6: TOL2 for lower sub-scheme**

<b>Lower sub-scheme transmission and operational loss allowance (ML)</b>		
<b>At 0% AAm</b>	<b>At 60% AAm</b>	<b>At 100% AAm</b>
100	400	550

**VIWY = Net total volume of unused water allocation transferred into the current water year from the previous water year**

VIWY is the net total volume of unused water allocation that is transferred into a water year from the previous water year, taking into account:

- The volume of water carried over to the current water year from the previous water year;
- The volume of water brought forward from the current water year to the previous water year; and
- The volume of water carried over to the current water year that had been supplied in the current water year as at the date of the assessment of the announced allocation.

# Attachment 4.1G

## Dawson Valley Water Supply Scheme Monitoring program

### 1 Water quantity

#### 1.1 Height and stream flow

The Resource Operations Licence (ROL) holder must record height and flow data in accordance with Table 1.

**Table 1: Locations in the Dawson River where height and flow data is required**

Location	Height data	Flow data
Glebe Weir inflow		✓
Glebe Weir storage	✓	
Glebe Weir outflow		✓
Gyranda Weir inflow		✓
Gyranda Weir storage	✓	
Gyranda Weir outflow		✓
Theodore Weir inflow		✓
Theodore Weir storage	✓	
Theodore Weir outflow		✓
Moura Weir inflow		✓
Moura Weir storage	✓	
Moura Weir outflow		✓
Neville Hewitt Weir inflow		✓
Neville Hewitt Weir storage	✓	
Neville Hewitt Weir outflow		✓

It is preferred that continuous time series data be collected. However, the chief executive may approve the collection of data in a format and standard other than for continuous time series data.

The methodology for determining height and flow data, including data format and standard, must be approved by the chief executive.

#### 1.1a Operating level of storages

The ROL holder must record for Glebe Weir, Gyranda Weir, Theodore Weir, Moura Weir and Neville Hewitt Weir:

- The daily storage height; and
- The daily storage outflow.

For the purposes of this section:

- The methodology for determining the daily storage height and daily storage outflow must be approved by the chief executive; and
- The data must be real time information upon which operational decisions were based not data that has subsequently changed for example through a verification process.

**1.1b Stream flow for the purpose of first post-winter flow management strategies**

The ROL holder must record for each storage where a first post-winter flow management strategy applies under Section 4 of Attachment 4.1E:

- The storage inflow;
- The storage height; and
- The storage outflow.

For the purposes of this section:

- The methodology for determining the storage inflow, storage height and storage outflow must be approved by the chief executive;
- The storage inflow, storage height and storage outflow are only required to be recorded for the duration of the implementation of the first post-winter flow management strategy; and
- The data must be real time information upon which operational decisions for the implementation of the strategy were based not data that has subsequently changed for example through a verification process.

**1.1c Stream flow for the purpose of seasonal base flow management strategies**

The ROL holder must record for each storage where a seasonal base flow management strategy applies under Section 5 of Attachment 4.1E:

- The daily storage inflow volume;
- The daily storage inflow volume adopted for the purpose of determining passing flow requirements under the rules for the seasonal base flow management strategy. That is, the inflow volume after any adjustment to account for water released from an upstream storage for maintaining storage heights or to supply water users, in accordance with the seasonal base flow rules;
- The daily storage height; and
- The daily storage outflow.

For the purposes of this section:

- The methodology for determining the daily storage inflow volume, daily storage inflow volume adopted for the purpose of determining passing flow requirements, daily storage height and daily storage outflow must be approved by the chief executive; and
- The data must be real time information upon which operational decisions for the implementation of the strategy were based not data that has subsequently changed for example through a verification process.

**1.2 Releases from storages**

The ROL holder must record details of the basis for each release decision for each storage under the rules for releases of water from storages given in Section 3 of Attachment 4.1E, including:

- The general rules for releases;
- The release rate rules;
- The first post-winter flow, seasonal base flow and fishway management strategies; and
- The quality of water released from storages.

The ROL holder must record the time, date and release rate each time a release rate is changed for each storage. In addition, for storages with a multi-level inlet, the ROL holder must record the level from which the release is made and the basis of the decision for determining that level.

The ROL holder must record the daily volume released (through the outlet/s and fishway) from each storage.

### **1.3 Announced allocations**

The ROL holder must record details of announced allocation determinations, referred to in Section 1 of Attachment 4.1F, including:

- The date and value for announced allocations, including the initial and any interim announced allocations; and
- The parameters applied for each announced allocation determination, including the initial and any interim announced allocations.

### **1.4 Critical water supply water sharing rules for 1 July to 30 September**

The ROL holder must record details of any limitations on the supply of water between 1 July and 30 September under the critical water supply water sharing rules in Section 2.1 of Attachment 4.1F, including:

- The date and extent of any volume limitations; and
- The parameters applied for the determination of any volume limitation.

### **1.5 Critical water supply water sharing rules for the supply of high priority water when medium A announced allocations are zero**

The ROL holder must record details of any restrictions on the supply of high priority water referred to in Section 2.2 of Attachment 4.1F, including:

- The date of the restriction;
- The nature of the restriction; and
- The basis for the determination of the restriction.

### **1.6 Transfer of water between water years**

The ROL holder must record details of the transfer of water between water years referred to in Section 3 of Attachment 4.1F, including:

- Scheme practices applied for carry over and forward draw of water entitlements;
- The basis of each decision to adjust the amount of water an individual may be supplied in a water year and the volume of the adjustment;
- The basis of each decision to approve a carry over or forward draw for each individual water user;
- The volume of water carried over from a water year to the next water year by sub-scheme; and
- The volume of water brought forward from the next water year to a water year by priority group and sub-scheme.

### **1.7 Seasonal water assignment**

The ROL holder must record details of individual seasonal water assignment arrangements.

### **1.8 Water taken by water users**

The ROL holder must record the volume of water taken by water users as follows:

- For each individual water user specified for each zone:
  - The total volume of supplemented water taken each quarter;
  - The total volume of supplemented water entitled to be taken at any time;
  - The basis for determining the total volume of supplemented water entitled to be taken at any time, including any adjustments for approved seasonal water assignments and transfers into or out of the water years;
  - The total volume of metered water taken as ‘riparian entitlement water’; and
  - The zone.

Water taken under a water allocation with purpose ‘distribution loss’ should be recorded as an individual water user.

### **1.9 Water diversions**

The ROL holder must record the daily volume of water diverted to:

- Gibber Gunyah channel system;
- Theodore channel system; and
- Moura Offstream Storage.

The methodology for determining the volume must be approved by the chief executive.

The ROL holder must record the start and end of each period of diversion to Moura Offstream Storage.

### **1.10 Waterholes**

The ROL holder must:

- Establish a unique identifier for any waterhole from which supplemented water is taken that is drawn down more than 0.6 metres below cease to flow level; and
- Record the water level in the waterhole each day that supplemented water is taken from the waterhole and the water level is more than 0.6 metres below the cease to flow level.

## **2 Impact of storage operation on aquatic ecosystems**

The ROL holder must undertake the following to establish any impacts on aquatic ecosystems that are potentially related to the operation of storages.

### **Section 2.1 Bank condition**

The ROL holder must inspect banks for evidence of collapse and/or erosion within the ponded area and downstream of storages following instances of rapid water level changes or large flows through storages, or other occasions when collapse and/or erosion of banks may be likely. The distance downstream is the distance of influence of storage operations.

Any instances of bank slumping or erosion observed must be investigated to determine if the instability was associated with the nature or operation of the infrastructure.

## **2.2 Water Quality**

The ROL holder must monitor water quality in relation to relevant infrastructure in accordance with the department's Water Monitoring Data Collection Standard.

## **2.3 This section not required**

## **2.4 Fish stranding**

The ROL holder must investigate instances of fish stranding downstream of storages to determine if the fish stranding is associated with operation of infrastructure. The distance downstream of storages is the distance of influence of storage operations.

## **3 Reporting**

There are four levels of reporting for ROL holders:

- Quarterly report for the previous quarter;
- Annual report for the previous water year;
- Operational reports; and
- Emergency reports.

### **3.1 Quarterly report**

The ROL holder must transfer the following data to the chief executive:

- Water quantity all records referred to in Sections 1.1a and 1.1c;
- Release from storages where applicable, the level from which releases were made referred to in Section 1.2;
- Water diversions daily volume of water diverted to Moura Offstream storage and the start and end of each period of diversion to Moura Offstream storage referred to in Section 1.9;
- Waterholes all records referred to in Section 1.10;
- A summary of bank condition monitoring and incidences of slumping referred to in Section 2.1;
- Water quality all records referred to in Section 2.2; and
- Seasonal water assignments all records referred to in section 1.7.

### **3.2 Annual report**

The annual report must include, but not be limited to, discussion and recommendations with regard to monitoring and assessment for the previous water year as follows.

#### **3.2.1 Water monitoring**

A summary of the implementation of the rules for releases from storages, other than for first post-winter flow, seasonal base flow, fishway management and quality of water released.

A summary of the implementation of the first post-winter flow and seasonal base flow management strategies for each applicable storage, including:

- Overview of strategy implementation, including the basis of decisions; and
- An evaluation of the first post-winter flow and seasonal base flow management arrangements and outcomes.

A summary of the implementation of the fishway management strategy for each applicable storage, including:

- Overview of strategy implementation;
- Periods of operation of the fishway; and
- Total period of operation of the fishway.

A summary of the implementation of the quality of water released from storages rules for each applicable storage, including:

- Overview of rule implementation;
- Basis of the decisions on the level from which to make releases; and
- Periods of release from each offtake level.

A summary of waterhole management including:

- Overview of waterhole management implementation; and
- Periods when the water level in a waterhole was more than 0.6 metres below its cease to flow level for more than 2 consecutive days and supplemented water was being taken.

A summary of announced allocation determinations, including:

- An evaluation of the announced allocation procedures and outcomes; and
- The date and value for each announced allocation.

A summary of the critical water supply water sharing rules, including:

- An evaluation of the rules and outcomes; and
- The date and nature of any limitations or restrictions on the volumes that may be supplied.

A summary of the transfer of water between water years specified by sub-scheme, including:

- An evaluation of rules and outcomes;
- The total volume of water carried over to the water year from the previous water year;
- The total volume of water carried over from the water year to the next water year;
- The total volume of water brought forward by priority group to the water year from the next water year; and
- The total volume of water brought forward by priority group from the water year to the previous water year.

A summary of the volumes of water taken by water users, specified by zone, including:

- The total volume of supplemented water taken;
- The total volume of supplemented water entitled to be taken;
- The basis for determining the total volume of supplemented water entitled to be taken, including any adjustments for approved seasonal water assignments and transfers into or out of the water years;
- The announced allocation volume at the end of the water year;
- The total volume of supplemented water taken between 1 July to 30 September; and

- The total volume of metered water taken as ‘riparian entitlement water’.

A summary of seasonal water assignment arrangements, including:

- An evaluation of the seasonal water assignment rules and outcomes, including:
  - An evaluation of any circumstances of supply difficulties when the supply difficulties were linked to seasonal water assignment practices; and
  - Identification of and reporting on any trends in seasonal assignment;
- The total number of seasonal water assignment arrangements; and
- The total volume of water seasonally assigned.

Details of changes to storages or their operation that may have an impact on the implementation of the ROP.

Details of new monitoring devices such as equipment to measure stream flow.

### **3.2.2 Impact of storage operation on aquatic ecosystems**

#### **Bank condition and fish stranding**

A summary of bank condition and fish stranding monitoring including:

- Results of investigations of bank slumping or erosion identified in ponded areas and downstream of storages;
- Results of any investigations of fish stranding downstream of storages; and
- Changes to operation of storages to reduce instances of bank slumping, erosion or fish stranding.

#### **Water quality**

Discussion and assessment of the following water quality issues:

- Thermal and chemical stratification in each storage;
- Water quality in each storage;
- Contribution of the storage and its management to the quality of water released;
- Cumulative effect of successive storages on water quality; and
- Cyanobacteria population changes in response to stratification in each storage.

### **3.3 Operational reports**

The ROL holder must notify the chief executive within 1 business day of becoming aware of the following operational incidents:

- Noncompliance by the ROL holder with the rules given in the ROP;
- A decision relating to each announced allocation;
- A decision to limit the supply of water between 1 July and 30 September;
- A decision relating to any restrictions on the taking of high priority water; and
- Instances of fish stranding downstream of a storage.

The ROL holder must provide an operational report to the chief executive for the following operational incidents:

- Noncompliance with the rules in the ROP; and
- Instances of fish stranding downstream of a storage.

The report must provide details of the incident, conditions under which the incident occurred and any responses or activities carried out as a result of the incident.

The ROL holder must provide an operational report to the chief executive within 5 business days after a decision relating to each announced allocation. The report should include the parameters applied referred to in Section 1.3.

The ROL holder must provide an operational report to the chief executive within 5 business days after a decision to limit the supply of water between 1 July and 30 September. The report should include the parameters applied referred to in Section 1.4.

The ROL holder must provide a report to the chief executive within 5 business days after implementation of a first post-winter flow management strategy ends. The report should include:

- Storage inflow, storage height and storage outflow records referred to in Section 1.1b.

### **3.4 Emergency report**

An emergency for the purpose of this ROP includes an occurrence, which by the nature of its severity, extent or timing might be regarded as an emergency (for example, contamination of water supply, structural damage to infrastructure or a danger to human health).

For any emergency, the ROL holder must:

- Notify the chief executive immediately; and
- Provide a report to the chief executive on the emergency including details of the emergency, conditions under which the emergency occurred, any responses or activities carried out as a result of the emergency and any impacts on the ROP.

# Attachment 4.1H

## Dawson Valley Water Supply Scheme

### Water allocation change rules

#### 1 Permitted changes

The permitted changes apply only to water allocations with purpose ‘agriculture’ or ‘any’.

Application for the following changes to a water allocation will be approved. On approval, a change certificate will be issued by the chief executive, which may be lodged with the registrar of water allocations.

##### 1.1 Location

Subject to Section 1.1.1, a change to the location of a water allocation from one of the following zones to any other of those zones:

- Dawson B;
- Dawson C;
- Dawson D.
- Dawson E;
- Dawson F;
- Dawson G;
- Dawson H;
- Dawson I;
- Dawson J;
- Dawson K;
- Dawson L; or
- Dawson M.

For the permitted changes to the location of a water allocation given in this section, conversion factors do not apply to the volume for the water allocation – that is, the volume for the water allocation will be the same before and after the change of location. However, this does not preclude consideration of conversion factors to enable changes under Section 3.

##### 1.1.1 Limitations on change of location

A proposed change is not a permitted change if the proposed change would result in a distribution of medium and high priority water allocations not provided for in Tables 1, 2, 3 and 4 (see Section 3 for proposed changes that can be processed under Section 130 of the Water Act).

If a location for a medium A priority water allocation is changed from Dawson I to another location, at the time the change of location is approved, the priority group will be set as medium.

## 1.2 Purpose

A change to the purpose of a water allocation from ‘any’ to ‘agriculture’ or from ‘agriculture’ to ‘any’.

## 1.3 Priority group

A change to the priority group of a water allocation from medium priority to medium A priority if the zone specified for the water allocation is Dawson I, provided:

- The proposed change would not cause the maximum volume in Table 4 to be breached.

## 1.4 Amalgamation or subdivision

A change to subdivide a water allocation provided:

- The sum of the nominal volumes of the new water allocations is equal to the nominal volume of the water allocation that is being subdivided; and
- The location and priority group of the new water allocations is the same as that of the water allocation that is being subdivided.

A change to amalgamate water allocations provided:

- The nominal volume of the new water allocation is equal to the sum of the nominal volumes of the water allocations that are being amalgamated;
- The location and priority group of the water allocations that are being amalgamated are the same; and
- The location and priority group for the new water allocation is the same as that of the water allocations that are being amalgamated.

**Table 1: Permitted distributions of high priority water allocations in zones Dawson M, L, K, J, I, H, G, F, E, D, C and B**

Volume of high priority water allocation (ML)	Dawson M & Dawson L	Dawson K & Dawson J	Dawson I & Dawson H	Dawson G, Dawson F & Dawson E	Dawson D, Dawson C & Dawson B
Minimum volume	0	200	662	3,119	998
Maximum volume	0	600	1,060	3,519	998

**Table 2: Permitted distributions of medium (including medium A) priority water allocations and interim water allocations in zones Dawson M, L, K, J, I, H, G, F, E, D, C and B**

Volume of medium priority water allocation (ML)	Dawson M & Dawson L	Dawson K & Dawson J	Dawson I & Dawson H	Dawson G, Dawson F & Dawson E	Dawson D, Dawson C & Dawson B
Minimum volume	560	6,350	25,500	9,450	6,838
Maximum volume	1,760	9,850	30,500	14,450	8,838

**Table 3: Maximum volumes of medium and high priority water allocations in specified zones**

Location (Zone)	Volume of high priority water allocation (ML)		Volume of medium priority water allocation (ML)	
	Volume on ROP approval	Maximum volume	Volume on ROP approval	Maximum volume
Dawson C	0	0	1,892	1,942
Dawson B	350	350	683	733

**Table 4: Minimum and maximum volumes of medium A priority water allocations in Zone Dawson I**

Location	Volume of medium A priority water allocation (ML)		
	Volume on ROP approval	Minimum volume	Maximum volume
Dawson I	19,456	3,405	19,456

## 2 Prohibited changes

The following changes are prohibited changes:

### 2.1 Location

A change to a location that is not within the extent of the Dawson Valley, Nogoia Mackenzie, Lower Fitzroy or Fitzroy Barrage water supply scheme.

### 2.2 Priority group

A change to a priority group that is not medium, medium A or high.

### 2.3 Purpose

A change to a purpose that is not 'agriculture' or 'any'.

## **2.4 Volume**

A change to the volume that is not a consequence of a change to another attribute of a water allocation.

## **2.5 Other**

A change that requires an amendment to this ROP, other than an amendment provided for in Chapter 8.

## **3 Application for change under Section 130 of the Water Act**

If a water allocation holder wishes to apply for a change to a water allocation that is not permitted under Section 1, and not prohibited under Section 2, an application may be made under Section 130 of the Water Act for the change.

The chief executive will deal with applications made under Section 130 of the Water Act, in accordance with the Water Act. That process is as follows:

- Notice of the application is published in local newspapers. The notice includes information about where the application can be inspected and invites submissions from the public on the application;
- The chief executive determines if the application should be approved having regard to the potential impact on a range of interests including other entitlement holders and aquatic ecosystems;
- If the chief executive approves the application, the chief executive will issue a change certificate that may be lodged with the registrar of water allocations; and
- If the chief executive refuses the application, the Water Act provides for an appeal process.

### **3.1 Purpose**

Any application to change the purpose of a water allocation from 'distribution loss' to 'any' must be supported by information to substantiate to the satisfaction of the chief executive an efficiency gain within the associated channel system. An application may be made for efficiency gains made since the issue of the interim resource operations licence for the Dawson Valley Water Supply Scheme in November 2000.

## **4 Registration of change**

If an application to change a water allocation is approved, the chief executive will issue a change certificate. The water allocation holder may lodge the change certificate with the registrar of water allocations who will change the water allocation on the water allocation register.

However, the registrar will not register the change until a supply contract has been entered into between the water allocation holder and the ROL holder for supply of the changed water allocation.

# Attachment 4.11

## Dawson Valley Water Supply Scheme

### Amending critical water supply management arrangements

#### 1 Critical water supply management arrangements

##### 1.1 Introduction

The Resource Operations Plan (ROP) rules for infrastructure operation and environmental management (refer Attachment 4.1E) and for water sharing (refer Attachment 4.1F) include arrangements for dealing with periods of low water availability. These arrangements are referred to as the critical water supply management arrangements.

The critical water supply management arrangements initially specified in the ROP are based on broad-scale basin-wide hydrologic modelling. These initial arrangements may need to be refined and further developed to ensure the arrangements appropriately deal with local issues and circumstances particular to the Dawson Valley Water Supply Scheme.

Over time the arrangements can also be amended to allow adaptation to changing circumstances and refinement through improved knowledge about the operation of the system at times of low water supply.

For example, the critical water supply water sharing rules given in Attachment 4.1F deal with situations when the full announced allocation entitlements cannot be supplied as a consequence of a substantial failure of a wet season. The initial arrangements for sharing the available supplies, including securing supplies for essential needs, may warrant ongoing development.

Variations to the rules associated with the minimum operating levels for storages and to the waterhole drawdown limits given in Attachment 4.1E may also be considered to accommodate local water user and environmental needs under particular circumstances.

##### 1.2 Criteria for critical water supply management arrangements

Critical water supply management arrangements must have regard to the following:

- Provision of water for essential water needs must have first priority;
- The objectives of the Water Resource Plan;
- The effects on water allocation security performance;
- The effects on natural ecosystems and the physical integrity of the watercourse; and
- The public interest.

For the purpose of the critical water supply management arrangements, essential water needs must include that part of a town water supply required for essential services including drinking water and sanitation but excluding lawns and gardens. The Resource Operations Licence (ROL) holder in conjunction with water allocation holders may establish additional essential purposes.

### **1.3 Initial review of the critical water supply management arrangements**

The ROL holder must undertake an initial review of the suitability of the critical water supply management arrangements. A report on the initial review must be provided to the chief executive within 6 months of the commencement of the ROP.

The initial review must include recommendations on whether amendments to the arrangements should be considered.

### **1.4 Proposals to amend the critical water supply management arrangements**

The ROL holder may submit a proposal to amend the critical water supply management arrangements at any time.

The chief executive may require the ROL holder to prepare a proposal to amend the critical water supply management arrangements at any time.

If the initial review of the critical water supply management arrangements under Section 1.3 indicates changes to the arrangements should be considered, the chief executive may require the ROL holder to prepare a proposal to amend the critical water supply management arrangements within a timeframe set by the chief executive.

A proposal to amend the critical water supply management arrangements must include:

- Proposed changes to the rules for infrastructure operation and environmental management (refer Attachment 4.1E) and for water sharing (refer Attachment 4.1F);
- An assessment of the effects of the proposal on natural ecosystems and the physical integrity of the watercourse and the proposed environmental monitoring requirements;
- Details of consultation with stakeholders including water users, local communities and environmental interests; and
- Any other information that will assist the chief executive to decide the proposal.

### **1.5 Amending the critical water supply management arrangements**

The chief executive may amend the rules for infrastructure operation and environmental management (refer Attachment 4.1E) and for water sharing (refer Attachment 4.1F) that apply during periods of low water availability. The chief executive will consider the following in deciding to amend the rules:

- Any proposal to amend the critical water supply management arrangements submitted by the ROL holder; and
- The criteria given in Section 1.2.

### **1.6 Evaluation of critical water supply management arrangements**

The ROL holder must annually evaluate the critical water supply management arrangements in regard to their suitability for periods of low water availability.

## Attachment 4.2A

# Attachment 4.2B

## Nogoa Mackenzie Water Supply Scheme

### Rules for conversion to water allocations

#### 1 Locations where existing authorisations are being converted to water allocations

Existing authorisations for supplemented water are being converted to water allocations on:

- The Nogoa River from the upstream limit of Fairbairn Dam to the Comet River junction;
- The Mackenzie River from the Comet River junction to the Springton Creek junction; and
- Sections of tributaries of these rivers that contain water ponded from natural waterholes or infrastructure within the above sections of the Nogoa and Mackenzie rivers.

#### 2 Rules for conversion of existing authorisations to water allocations

The following rules apply for the conversion of existing authorisations to water allocations to establish the details required for the registration of supplemented water allocations.

##### 2.1 Location

The location from which water may be supplied under a water allocation is specified as a zone according to the position of the existing authorisation. Descriptions of the zones for the Nogoa and Mackenzie rivers are given in Attachment 2.2.

##### 2.2 Purpose

The purpose for which water may be taken under a water allocation is specified as 'agriculture', 'distribution loss' or 'any'. 'Agriculture' is the nominated purpose for those existing authorisations that are primarily used for agricultural purposes. 'Distribution loss' is the nominated purpose for water allocations for distribution losses associated with the Selma and Weemah channel systems and Blackwater pipeline. 'Any' is the nominated purpose for all other uses of water.

##### 2.3 Volume

The nominal volume for a water allocation will be the volume stated on existing authorisations subject to the following arrangements for entitlements associated with watering stock normally depastured on the land and domestic purposes.

Under the Water Act, an owner of land adjoining a watercourse, lake or spring may take water for domestic purposes and watering stock that would be normally depastured on the land without a water entitlement. Therefore any existing authorisation that provides for the taking of water for stock and domestic purposes on land adjoining a watercourse will not be converted to a water allocation.

**2.3.1 Arrangements for authorisations for irrigation and stock and domestic purposes**

- a) For an authorisation for irrigation, stock and domestic purposes, where all the land supplied adjoins a watercourse:
- If the authorisation states an irrigation volume and a stock and domestic volume, the irrigation volume is the volume for the water allocation; or
  - If the authorisation states an irrigation volume but not a stock and domestic volume, the irrigation volume is the volume for the water allocation.
- b) For an authorisation for irrigation, stock and domestic purposes, where all the land supplied does not adjoin a watercourse:
- If the authorisation states an irrigation volume and a stock and domestic volume, the combined irrigation volume and stock and domestic volume is the total volume for the water allocation; or
  - If the authorisation states an irrigation volume but not a stock and domestic volume, the irrigation volume is the volume for the water allocation.
- c) For an authorisation for irrigation, stock and domestic purposes, where part of the land supplied is not contiguous with the land that adjoins a watercourse:
- If the authorisation states an irrigation volume and a stock and domestic volume, the combined irrigation volume and the calculated volume for stock and domestic purposes on the non-adjoining land is the volume for the water allocation; or
  - If the authorisation states an irrigation volume but not a stock and domestic volume, the irrigation volume is the volume for the water allocation.
- d) For an authorisation for stock and domestic purposes only, where all the land supplied does not adjoin a watercourse:
- If the authorisation states a stock and domestic volume, the stock and domestic volume is the volume for the water allocation; or
  - If the authorisation does not state a stock and domestic volume, the annual volume calculated for stock and domestic purposes is the volume for the water allocation.
- e) For Section 2.3.1c) and Section 2.3.1d), the annual volume calculated for domestic purposes is:
- i) 1 ML; or
  - ii) An alternative volume determined by the chief executive based on consideration of a submission received on this matter on the draft Resource Operations Plan (ROP).
- f) For Section 2.3.1c) and Section 2.3.1d), the annual volume calculated for stock watering is:
- i) A volume equivalent to 1 ML per 250 ha of land; or
  - ii) An alternative volume determined by the chief executive based on consideration of a submission received on this matter on the draft ROP.

Where an existing authorisation does not state a stock and domestic volume, the annual volume specified for the water allocation is the combined volume calculated using Section 2.3.1e)i) and Section 2.3.1f)i).

## **2.4 Priority group**

The priority group for a water allocation converted from an existing authorisation to take supplemented water is medium priority, except where a product specification or other undertaking associated with the authorisation identifies the authorisation's water supply as being high priority water allocation.

## Attachment 4.2C

### Nogoa Mackenzie Water Supply Scheme

### Total volume of supplemented water allocations

**Table 1: Total volume of supplemented water allocations at Resource Operations Plan approval**

Zone	Medium priority water allocation (ML)	High priority water allocation (ML)
<b>Mackenzie N</b>	125,239 (note 1)	8,589 (note 2)

<b>Mackenzie B</b>	1,260	0
<b>Total</b>	<b>190,925</b>	<b>44,398</b>

*Note 1: Includes 155 ML to be granted to SunWater under Section 6.2.7 of Chapter 6.*

*Note 2: Includes 45 ML to be granted to SunWater under Section 6.2.7 of Chapter 6.*

# Attachment 4.2D

## Nogoa Mackenzie Water Supply Scheme Infrastructure details

### Storage: Fairbairn Dam – Nogoa River AMTD 685.6 km

Description of water infrastructure	
Main embankment	Earth fill dam
Full supply level	EL 204.23 m AHD
Fixed crest level	EL 204.23 m AHD
Saddle dam(s)	Six saddle dams. Saddle dam 3 has a concrete chute spillway
Fabridams	Nil
Gates	Nil
Storage volume and surface area	
Full supply volume	1,301,000 ML
Dead storage volume	12,300 ML
Surface area/elevation and storage volume/elevation relationship	Natural Resources Drawing No. A3-203831 & A3-203832 (19/09/96)
Spillway arrangement	
Description of works	Curved approach channel to a mass concrete ogee crest. Concrete lined chute with energy dissipaters.
Spillway level	EL 204.23 m AHD
Spillway width	167.64 metres
Discharge characteristics	Irrigation and Water Supply Commission spillway discharge curve No. L42944 1054-D1189 (Aug 1974)
River inlet/outlet works	
Description of works	An intake tower, equipped with two 1200 mm by 1800 mm regulating gates, diverting under gravity via a 6.1 metre diameter tunnel to headworks controlled by 1 vertical lift gate for releases to the Nogoa River  Methods may be employed to enable a maximum discharge capacity of up to 400 ML/day when the level of water stored in Fairbairn Dam is between EL190.21 m AHD and EL185.85 m AHD.
Multi-level inlet	Works do not accommodate selective withdrawal.
Cease to flow level	EL 190.21 m AHD (river outlet)
Discharge characteristics	Right bank outlet (River & Weemah Channel) L42946 1054-D1191 (Aug 1974) The existing maximum discharge capacity of the river outlet is approximately 600 ML/day. <i>Note: Chapter 8 provides for the river outlet to be modified to accommodate an increased discharge capacity to up to 1,600 ML/day.</i>
Fish transfer system	
Description of works	Nil

**Storage: Selma Weir – Nogoia River AMTD 668.7 km**

<b>Description of water infrastructure</b>	
Main embankment	Mass concrete weir
Full supply level	EL 170.39 m AHD
Fixed crest level	EL 170.39 m AHD
Saddle dam(s)	Nil
Fabridams	Nil
Gates	Nil
<b>Storage volume and surface area</b>	
Full supply volume	1180 ML
Dead storage volume	25 ML
Surface area/elevation and storage volume/elevation relationship	Drawing No. F35379 (27/6/73)
<b>Spillway arrangement</b>	
Description of works	Mass concrete ogee crest
Spillway level	EL 170.39 m AHD
Spillway width	From left to right along structure: EL 170.39 m AHD (der) – Length 23.77 metres EL 171.92 m AHD (der) – Length 54.86 metres EL 171.31 m AHD (der) – Length 34.75 metres EL 171.00 m AHD (der) – Length 34.75 metres
Discharge characteristics	Irrigation and Water Supply Commission Drawing No. F-12400 (5/3/54)
<b>River inlet/outlet works</b>	
Description of works	Outlet works: 300 mm RC pipe with a gate valve at the concrete outlet box
Multi-level inlet	Single-level offtake only
Cease to flow level	Outlet works: Invert EL 165.52 m AHD
Discharge characteristics	Maximum discharge capacity of approximately 35 ML/day
<b>Fish transfer system</b>	
Description of works	Nil

**Storage: Bedford Weir – Mackenzie River AMTD 548.8 km**

<b>Description of water infrastructure</b>	
Main embankment	Mass concrete weir with fabridam
Full supply level	EL 124.0 m AHD
Fixed crest level	EL 122.80 m AHD
Saddle dam(s)	Nil
Fabridams	1.2 m fabridam
Gates	Nil
<b>Storage volume and surface area</b>	
Full supply volume	22,900 ML
Dead storage volume	3,290 ML
Surface area/elevation and storage volume/elevation relationship	Department of Primary Industries (Water Resources) Storage Curve No. A3-110858A (22/3/96)
<b>Spillway arrangement</b>	
Description of works	Reinforced concrete crest (with deflated dam)
Spillway level	EL 122.80 m AHD
Spillway width	185.90 metres
Discharge characteristics	Ref: SWP ES, Bedford Weir Stage 2 Weir Operation, July 97
<b>River inlet/outlet works</b>	
Description of works	Original outlet works: Concrete outlet recess. 750 mm diameter RC pipe reducing to 450 mm diameter RC pipe controlled by a gate valve on the downstream end. New outlet works: 1200 mm by 1200 mm square unlined conduit cut from the original mass concrete monolith, controlled by 1200 mm by 1200 mm roller gate.
Multi-level inlet	New inlet works have selective withdrawal capabilities.
Cease to flow level	Original outlet works: EL 112.88 m AHD New outlet works: EL 116.08 m AHD
Discharge characteristics	Maximum design discharge capacity of original outlet 160 ML/day Maximum design discharge capacity of new outlet 890 ML/day Ref: SWP ES, Bedford Weir Stage 2 Weir Operation, July 97
<b>Fish transfer system</b>	
Description of works	Nil

**Storage: Bingegang Weir – Mackenzie River AMTD 489.2 km**

<b>Description of water infrastructure</b>	
Main embankment	Mass concrete weir
Full supply level	EL 102.90 m AHD
Fixed crest level	EL 102.90 m AHD
Saddle dam(s)	Nil
Fabridams	Nil
Gates	Nil
<b>Storage volume and surface area</b>	
Full supply volume	8,060 ML
Dead storage volume	1,400 ML
Surface area/elevation and storage volume/elevation relationship	Natural Resources Storage Curve No. A3-110940 (22/5/96)
<b>Spillway arrangement</b>	
Description of works	Reinforced concrete crest
Spillway level	EL 102.90 m AHD

# Attachment 4.2E

## Nogoa Mackenzie Water Supply Scheme

### Rules for infrastructure operation and environmental management

#### 1 Operating levels of storages and waterholes

##### 1.1 Nominal operating levels of storages

The nominal operating level for each storage in the scheme is given in Table 1.

Releases must be made from the relevant upstream storage given in Table 1 to maintain the water level in a storage at its nominal operating level, unless the water level in Fairbairn Dam is below EL 191.0 m AHD (92,900 ML).

Storage levels may vary above and below the nominal operating level due to practical limitations of estimating and making releases and for unforeseen circumstances.

**Table 1: Nominal operating levels of storages**

Storage	Upstream storage	Nominal operating level
Fairbairn Dam	Not Applicable	Not Applicable
Selma Weir	Fairbairn Dam	EL 169.89 m AHD (900 ML)
Bedford Weir	Fairbairn Dam	EL 118.38 m AHD (6,500 ML)
Bingegang Weir	Bedford Weir	EL 99.94 m AHD (3,100 ML)
Tartrus Weir	Bingegang Weir	EL 79.25 m AHD (6,160 ML)

##### 1.2 Minimum operating level of storages

The minimum operating level for each storage in the scheme are given in Table 2.

**Table 2: Local supply areas and minimum operating levels of storages**

Storage	Local supply area	Minimum Operating Levels
Fairbairn Dam	Fairbairn Dam pond and downstream to, but excluding, Bedford Weir pond	EL 185.85 m AHD
Selma Weir	Not applicable	EL 165.52 m AHD
Bedford Weir	Bedford Weir pond and downstream to, but excluding, Bingegang Weir pond	EL 115.08 m AHD
Bingegang Weir	Bingegang Weir pond and downstream to, but excluding, Tartrus Weir pond	EL 97.74 m AHD
Tartrus Weir	Tartrus Weir pond and downstream to Springton Creek junction	EL 76.85 m AHD

Water must not be released or supplied from a storage if the water level in that storage is below its minimum operating level, unless otherwise authorised by the chief executive.

Bedford Weir may be drawn down to its minimum operating level only if Fairbairn Dam is below EL 191.0 m AHD (92,900 ML).

Bingegang Weir may be drawn down to its minimum operating level only if Bedford Weir is below its nominal operating level.

Tartus Weir may be drawn down to its minimum operating level only if Bingegang Weir is below its nominal operating level.

### 1.3 Minimum levels in waterholes

For the waterholes listed in Table 3:

- Supplemented water must not be taken from a waterhole that is below the level stated in Table 3, unless otherwise authorised by the chief executive.

**Table 3: Drawdown levels for specific waterholes within the area of the Nogoia Mackenzie Water Supply Scheme**

Waterhole AMTD and local name (see note re AMTD)	Allowable drawdown below cease to flow level of waterhole (m)
436.6 to 467.2 km (downstream of Bingegang Weir)	0.9
Tartus Weir - 419.2 km (downstream of Tartus Weir)	1.0
412.3 km	1.0
408.5 km	1.0
378.8 km	1.0
373.2 km (10 Mile Waterhole)	1.0
371.3 km (10 Mile Waterhole)	1.0
357.9 km (at end of scheme)	1.0

*The waterhole referred to is that waterhole for which the stated AMTD is inclusive*

For a waterhole within the extent of the Nogoia Mackenzie Water Supply Scheme other than a waterhole listed in Table 3:

- Supplemented water should not be taken from a waterhole that is more than 0.5 metres below its cease to flow level; and
- The chief executive may authorise supplemented water to be supplied from a waterhole when the level is more than 0.5 metres below its cease to flow level.

## 2 Releases of water from storages

### 2.1 General rules

When determining releases from a storage, the ROL holder must have regard to the following:

- Total volume of water ordered, and its distribution;
- The rules for the supply of water orders in zone Mackenzie I, H, G, F and E, when the total volume of medium and high priority water allocations in those zones exceeds 33,000 ML;
- The likely contribution of inflows from tributaries that could assist the supply of orders;
- The likely transmission and operating losses;

- The travel time for water delivery;
- The volume of releases required to maintain nominal operating levels in downstream storages, and to maintain levels in waterholes;
- The first post-winter flow management strategy;
- The seasonal base flow management strategy; and
- The quality of water released from storages.

The ROL holder may incorporate provisions in supply contracts for circumstances when the release capacity of a storage is insufficient to meet downstream demand.

## 2.2 Release rate rules

Water may be released from a storage at a rate up to the maximum discharge capacity of its outlet works.

The maximum discharge capacity of the outlet works is to be used for meeting downstream demand or passing environmental flows as required.

A change to the rate of a release through the outlet works of a storage must have regard to the limits described in Table 4.

**Table 4: Limits on changes to rate of release through the outlet works of storages**

Storage	Limits on changes to rate of release through outlet works
Fairbairn Dam, Selma Weir, Bedford Weir, Bingeang Weir, and Tartrus Weir	<ul style="list-style-type: none"> <li>• Reductions of release rate must occur incrementally, such that the risk of fish stranding and bank slumping is minimised.</li> <li>• Maximum rates of increase in release rate are not specified.</li> </ul>

## 2.3 Bedford Weir fabridam deflation/inflation rules

Inflation and deflation of the Bedford Weir fabridam must occur incrementally, such that the risk of fish stranding and bank slumping is minimised.

## 2.4 Rules for the supply of water orders in zone Mackenzie I, H, G, F and E

### 2.4.1 Fairbairn Dam

This section only applies if:

- The total volume of medium and high priority water allocations in zone Mackenzie I, H, G, F and E exceeds 33,000 ML at the start of the water year;
- The level in Bedford Weir is between nominal operating level (EL 118.38 m AHD) and EL 123.5 m AHD;
- The level in Bingeang Weir is between nominal operating level (99.94 m AHD) and EL 102.4 m AHD; and
- The level in Fairbairn Dam is above EL 195.1 m AHD (300,000 ML).

If the total volume of medium and high priority water allocation in zone Mackenzie I, H, G, F and E exceeds 33,000 ML:

- Releases must be made from Fairbairn Dam to meet a portion of the volume of water ordered in zones Mackenzie I, H, G, F and E; and
- The volume of water ordered in zones Mackenzie I, H, G, F and E to be met by releases from Fairbairn Dam must be determined from the following relationship:

$$\text{FDO(Fairbairn)} = (\text{X} - 31,000) * \text{TD1/X}$$

Where:

FDO(Fairbairn) is the volume of water ordered in zones Mackenzie I, H, G, F and E that must be met by releases from Fairbairn Dam.

X is the total nominal volume for all medium and high priority water allocations in zones Mackenzie I, H, G, F and E at the start of the water year, adjusted by the net volume of medium and high priority water seasonally assigned into or out of this zone grouping to date since the start of the water year.

TD1 is the total volume of water ordered in zones Mackenzie I, H, G, F and E.

For the purpose of this rule:

- Volumes of water to be released under this rule may be accumulated up to 200 ML to improve the efficiency and effectiveness of the release.

#### 2.4.2 Bedford Weir

This section only applies if:

- The total volume of medium and high priority water allocations in zone Mackenzie I, H, G, F and E exceeds 33,000 ML at the start of the water year;
- The level in Bedford Weir is between nominal operating level (EL 118.38 m AHD) and EL 123.5 m AHD;
- The level in Bingegang Weir is between nominal operating level (99.94 m AHD) and EL 102.4 m AHD; and
- The level in Fairbairn Dam is above EL 195.1 m AHD (300,000 ML).

If the total volume of medium and high priority water allocation in zones Mackenzie I, H, G, F and E exceeds 33,000 ML:

- Releases must be made from Bedford Weir to meet a portion of the volume of water ordered in zones Mackenzie G, F and E; and
- The volume of water ordered in zones Mackenzie G, F and E to be met by releases from Bedford Weir must be determined from the following relationship:

$$\text{FDO(Bedford)} = \text{FDO(Fairbairn)} * \text{TD2/TD1}$$

Where:

FDO(Bedford) is the volume of water ordered in zones Mackenzie G, F and E that must be met by releases from Bedford Weir.

FDO(Fairbairn) is the volume of water ordered in zones Mackenzie I, H, G, F and E that must be met by releases from Fairbairn Dam determined under Section 2.4.1.

TD2 is the total volume of water ordered in zones Mackenzie G, F and E.

TD1 is the total volume of water ordered in zones Mackenzie I, H, G, F and E.

For the purpose of this rule:

- Volumes of water to be released under this rule may be accumulated up to 200 ML to improve the efficiency and effectiveness of the release.

### **3 First post-winter flow management strategy**

#### **3.1 Node 11 (Carnangarra) first post-winter flow management strategy**

##### **3.1.1 Notification of activation of strategy**

The Node 11 (Carnangarra) first post-winter flow management strategy is activated when the chief executive notifies the Nogo Mackenzie Water Supply Scheme ROL holder that the strategy is activated.

The chief executive will activate the first post-winter flow management strategy for the first flow event with the following attributes:

- General stream flow level rises of at least 1.5 metres in the Mackenzie River between the Comet River junction and the effective upstream limit of Bedford Weir between 1 October and 10 April, to indicate circumstances that would potentially trigger ecological processes associated with the first post-winter flow; or
- General stream flow level rises of at least 1.5 metres in the Mackenzie River between the Comet River junction and the effective upstream limit of Bedford Weir after 14 September, to indicate circumstances that would potentially trigger ecological processes associated with the first post-winter flow, provided that the water temperature is expected to be above the critical level for these processes; and
- Flow characteristics that would typically indicate an event resulting in flows between the Comet River junction and the effective upstream limit of Bedford Weir with a duration greater than the base flow of at least 15 days, to support ecological processes associated with the intent of the first post-winter flow.

The following guidelines will apply to evaluation of these flow attributes and in making a decision to activate the first post-winter flow management strategy:

- The ecological processes trigger will generally be identified by a rise in stream flow of at least 2,500 ML/day in the Mackenzie River immediately downstream of the Comet River junction.
- For an event with the ecological processes trigger occurring in September, the water temperature should be at least 23°C; and
- The characteristics of the flow event will be evaluated to decide whether the event would typically result in extended periods of flow immediately downstream of the Comet River junction above the base flow (the Water Resource Plan (WRP) specifies a base flow of 156 ML/day at the Comet River junction). This evaluation will be based on stream flow as well as Bureau of Meteorology weather and rainfall information.

The decision to activate the first post-winter flow management strategy will typically be made

within 3 days of the occurrence of the ecological process trigger flow. However the decision may occur later if subsequent weather, rainfall and runoff conditions indicate that the flow duration attributes could be achieved.

The department will prepare work practices that further guide evaluations associated with the activation of the first post-winter flow management strategies. These guidelines will be regularly reviewed to adapt to technological advances and operational experience.

### **3.1.2 Strategy details**

Releases to pass flows under the Node 11 (Carnangarra) first post-winter flow management strategy are in addition to any releases required for water supply or for maintaining operating levels in downstream weirs.

#### **(a) Fairbairn Dam**

The ROL holder must implement the node 11 (Carnangarra) first post-winter flow management strategy at Fairbairn Dam within 1 day of the activation of the strategy by the chief executive.

For 19 days from the date that implementation of the strategy begins at Fairbairn Dam, inflows to Fairbairn Dam must be passed as they occur, except:

- Releases must not be made if the water level in Fairbairn Dam is below EL 195.1 m AHD (300,000 ML);
- Releases are not required when Fairbairn Dam overflow is more than 220 ML/day; and
- Releases are not required when Fairbairn Dam inflow is less than 20 ML/day.

For the purpose of implementing the strategy:

- The passing flow may vary above and below that required under this strategy due to practical limitations of estimating and making releases, the maximum discharge capacity of the outlet works, and for unforeseen circumstances;
- The shape of the passing flow hydrograph should follow as far as practicable the shape of the inflow hydrograph; and
- At those times when the maximum discharge capacity of the outlet works limits the ability to pass inflows, the excess inflow volume will be retained in storage.

### **3.2 Node 10 (Bingegang) first post-winter flow management strategy**

#### **3.2.1 Notification of activation of strategy**

The Node 10 (Bingegang) first post-winter flow management strategy is activated when the chief executive notifies the Nogoia Mackenzie Water Supply Scheme ROL holder that the strategy is activated.

The chief executive will activate the first post-winter flow management strategy for the first flow event with the following attributes:

- General stream flow level rises of at least 1.5 metres in the Mackenzie River between Bedford Weir and the effective upstream limit of Tartrus Weir between 1 October and 10 April, to indicate circumstances that would potentially trigger ecological processes associated with the first post-winter flow; or

- General stream flow level rises of at least 1.5 metres in the Mackenzie River between the Bedford Weir and the effective upstream limit of Tartrus Weir after 14 September, to indicate circumstances that would potentially trigger ecological processes associated with the first post-winter flow, provided that the water temperature is expected to be above the critical level for these processes; and
- Flow characteristics that would typically indicate an event resulting in flows between Bedford Weir and the effective upstream limit of Tartrus Weir with a duration greater than the base flow of at least 15 days, to support ecological processes associated with the intent of the first post-winter flow.

The following guidelines will apply to evaluation of these flow attributes and in making a decision to activate the first post-winter flow management strategy:

- The ecological processes trigger will generally be identified by a rise in stream flow of at least 2,500 ML/day in the Mackenzie River immediately downstream of the Bingegang Weir.
- For an event with the ecological processes trigger occurring in September, the water temperature should be at least 23°C; and
- The characteristics of the flow event will be evaluated to decide whether the event would typically result in extended periods of flow immediately downstream of the Bingegang Weir above the base flow (the WRP specifies a base flow of 163 ML/day at the Bingegang Weir). This evaluation will be based on stream flow as well as Bureau of Meteorology weather and rainfall information.

The decision to activate the first post-winter flow management strategy will typically be made within 3 days of the occurrence of the ecological process trigger flow. However, the decision may occur later if subsequent weather, rainfall and runoff conditions indicate that the flow duration attributes could be achieved.

The department will prepare work practices that further guide evaluations associated with the activation of the first post-winter flow management strategies. These guidelines will be regularly reviewed to adapt to technological advances and operational experience.

### **3.2.2 Strategy details**

The ROL holder must implement the node 10 (Bingegang) first post-winter flow management strategy at Bedford Weir within 1 day of the activation of the strategy by the chief executive.

For 21 days from the date that implementation of the strategy begins at Bedford Weir, inflows to Bedford Weir must be passed as they occur, except:

- Releases must not be made if the water level in Bedford Weir is below EL 118.86 m AHD (7,500 ML);
- Releases are not required when Bedford Weir overflow is more than 220 ML/day; and
- Releases are not required when Bedford Weir inflow is less than 50 ML/day.

For the purpose of implementing the strategy;

- The passing flow may vary above and below that required under this strategy due to practical limitations of estimating and making releases, the maximum discharge capacity of the outlet works, the operational limitations of the fabridam, and for unforeseen circumstances;

- The shape of the passing flow hydrograph should follow as far as practicable the shape of the inflow hydrograph;
- At those times when the maximum discharge capacity of the outlet works limits the ability to pass inflows, the excess inflow volume will be retained in storage;
- The ROL holder must, by 31 July 2006, submit to the chief executive for approval proposed operating arrangements for the inflation of the fabridam during implementation of this strategy. The submission must include an assessment of the impact of the inflation of the fabridam on flow; and
- During implementation of this strategy, inflation of the fabridam must be consistent with arrangements approved by the chief executive.

#### **4 Seasonal base flow management strategy**

##### **4.1 Bedford Weir seasonal base flow management strategy**

A seasonal base flow equal to the inflow to Bedford Weir must pass Bedford Weir if:

- Inflows to the weir are between 100 ML/day and 220 ML/day;
- The water level in the weir is above EL 118.86 m AHD (7,500 ML); and
- The Node 10 (Bingegang) first post-winter flow management strategy is not in effect.

A seasonal base flow of 220 ML/day must pass Bedford Weir if:

- Inflows to the weir are greater than 220 ML/day;
- The water level in the weir is above EL 118.86 m AHD (7,500 ML); and
- The Node 10 (Bingegang) first post-winter flow management strategy is not in effect.

Seasonal base flow passed through Bedford Weir is in addition to any release required for supply between Bedford Weir and the Bingegang Weir pond.

For the purpose of implementing this strategy:

- The volume passed over a 48-hour period must be within plus 20% and minus 20% of the volume required to be passed under the strategy;
- The commencement and cessation of any release required under this strategy may be delayed by up to 48 hours; and
- Inflows to the weir do not include any water which was released from Fairbairn Dam intended to maintain the level in Bedford Weir at its nominal operating level or to supply users between Fairbairn Dam and the Bedford Weir pond.

##### **4.2 Bingegang Weir seasonal base flow management strategy**

A seasonal base flow equal to the inflow to Bingegang Weir must pass Bingegang Weir if:

- Inflows to the weir are between 100 ML/day and 220 ML/day;
- The water level in the weir is above EL 100.34 m AHD (3,500 ML); and
- The Node 10 (Bingegang) first post-winter flow management strategy is not in effect.

A seasonal base flow of 220 ML/day must pass Bingegang Weir if:

- Inflows to the weir are greater than 220 ML/day;
- The water level in the weir is above EL 100.34 m AHD (3,500 ML); and
- The Node 10 (Bingegang) first post-winter flow management strategy is not in effect.

Seasonal base flow passed through Bingegang Weir is in addition to any release required for supply between Bingegang Weir and the Tartrus Weir pond.

For the purpose of implementing this strategy:

- The volume passed over a 48-hour period must be within plus 20% and minus 20% of the volume required to be passed under the strategy;
- The commencement and cessation of any release required under this strategy may be delayed by up to 48 hours; and
- Inflows to the weir do not include any water which was released from Bedford Weir intended to maintain the level in Bingegang Weir at its nominal operating level or to supply users between Bedford Weir and the Bingegang Weir pond.

#### **4.3 Tartrus Weir seasonal base flow management strategy**

A seasonal base flow equal to the inflow to Tartrus Weir must pass Tartrus Weir between 1 September and 31 December if:

- Inflows to the weir are between 150 ML/day and 240 ML/day; and
- The water level in the weir is above EL 81.36 m AHD (11,000 ML).

A seasonal base flow of 240 ML/day must pass Tartrus Weir between 1 September and 31 December if:

- Inflows to the weir are greater than 240 ML/day; and,
- The water level in the weir is above EL 81.36 m AHD (11,000 ML).

Seasonal base flow passed through Tartrus Weir is in addition to any release required for supply between Tartrus Weir and the Springton Creek.

For the purpose of implementing this strategy:

- The volume passed over a 48-hour period must be within plus 20% and minus 20% of the volume required to be passed under the strategy;
- The commencement and cessation of any release required under this strategy may be delayed by up to 48 hours; and
- Inflows to the weir do not include any water which was released from Bingegang Weir intended to maintain the level in Tartrus Weir at its nominal operating level or to supply users between Tartrus Weir and the Springton Creek junction.

#### **5 Fishway management strategy**

There are no fishways in the scheme.

#### **6 Quality of water released from storages**

Where a storage incorporates a multi-level outlet, the ROL holder must draw water from the level that optimises the quality of the water released (for example, dissolved oxygen concentration and the temperature in the release water optimised), to minimise the impact on the downstream water quality. If this level does not provide enough capacity for the required release, other levels must be used to give the required discharge.

## **7 Use of watercourses for distribution of water**

The ROL holder may use the following watercourses for the purposes of distribution of water:

- The Nogoia River from the upstream limit of Fairbairn Dam to the Comet River junction;
- The Mackenzie River from the Comet River junction to the Springton Creek junction;
- Sections of tributaries of these rivers that contain water from natural waterholes and infrastructure within the above sections of the Nogoia and Mackenzie rivers; and
- The Comet River from AMTD 10.0 km to the Mackenzie River junction.

## **8 Use of unsupplemented watercourses for delivery of supplemented water**

The ROL holder may use the following unsupplemented watercourses for the purpose of delivery of supplemented water under the specified conditions:

### **8.1 Retreat Creek**

Retreat Creek from the confluence of Drain RR6 (approximately AMTD 9.5 km) to the Blair Athol Railway line crossing of Retreat Creek (approximately AMTD 3.0).

The ROL holder is responsible for metering of all supplemented water supplied from Retreat Creek.

For any day, the amount of supplemented water supplied by the ROL holder must not exceed the amount of supplemented water released to Retreat Creek by the ROL holder. For any day, the amount of water taken from Retreat Creek in excess of the amount of water released is unsupplemented water.

## **9 Riparian stock and domestic use**

Under Section 20(3) of the Water Act, an owner of land adjoining a watercourse, lake or spring may take water for domestic purposes and watering stock that would be normally depastured on the land without a water entitlement. In this section this is referred to as 'riparian entitlement water'.

This means that riparian entitlement water might also be taken through the same metered water facilities as supplemented water and some users might desire appropriate allowances be made for their riparian entitlement use. The historical arrangements for accounting for individual riparian use taken through metered facilities will not apply following commencement of the ROP.

### **9.1 Rules for adjusting metered use for riparian entitlement water use**

This section provides arrangements to allow adjustments for riparian entitlement water metered use.

The ROL holder must enter into an arrangement with any water user who requests metered use adjustments for riparian entitlement water use taken through a metered facility. The ROL holder must supply details of the arrangements with each individual user to the chief executive within 5 business days of an agreement.

An arrangement must comply with the departmental guidelines for this purpose.

If the ROL holder and a water user are unable to reach agreement on an arrangement, the chief executive will decide the arrangement that will apply in that particular instance.

# Attachment 4.2F

## Nogoa Mackenzie Water Supply Scheme

### Water sharing rules

This attachment provides water sharing rules for:

- Announced allocations;
- Critical water supply;
- Transfer of water between water years; and
- Seasonal water assignments.

There are two types of water allocation proposed to be supplied to water users in the Nogoa Mackenzie Water Supply Scheme, medium and high priority water allocations. The water sharing rules specify the way the water resources of the Nogoa Mackenzie Water Supply Scheme will be shared between each of the water allocation priority groups.

#### 1 Announced allocation

The announced allocation percentage is the percentage of the water allocation volume that may be supplied during the water year.

The Resource Operations Licence (ROL) holder is required to calculate announced allocation percentages for each priority group through the use of formulas and associated parameters. Details for each parameter used are specified in Section 5.

The amount of water that can be apportioned to each of the priority groups at any given time is determined by taking into account a number of factors, including:

- The time of year an assessment is made;
- The amount of water used by each priority group in the current water year up to the date of the assessment;
- The amount of water stored in Fairbairn Dam and the weirs;
- Allowance for evaporative and seepage losses from Fairbairn Dam and the weirs;
- Allowance for future inflows;
- Allowance for the requirements of high priority water allocation in future water years;
- Allowance for transmission and operational losses along the river; and
- The net amount of water allocation moved into the current water year from the previous water year.

The values for these factors applied in the announced allocation formula seek to maximise the availability of medium priority water allocation and secure the reliability for high priority water allocations as determined by testing in the department's hydrologic model (IQQM) over the long-term historical period. Importantly, the values given for these factors should not be taken out of the context of their purpose as part of the overall package used to determine the announced allocation.

## 1.1 General rules for announced allocations

The water year for the Nogoia Mackenzie Water Supply Scheme is from 1 July to 30 June in the following year.

Separate assessment of announced allocation percentages must be made for each priority group.

The initial announced allocation percentage for a water year must be announced within 2 weeks after the start of that water year.

The ROL holder may announce an interim announced allocation at any time during the water year. An interim announced allocation percentage must not be greater than the percentage that would be calculated using the formulas in Section 1.2. An interim announced allocation has effect as if it was an announced allocation calculated using the formulas in Section 1.2.

The ROL holder must announce an interim announced allocation immediately prior to the commencement of a water year. The basis/criteria for the determination of the interim announced allocation for the start of the water year must take into account water user requirements, and be made available to water users.

Announced allocation percentages must not be reduced during a water year.

Announced allocation percentages must not be greater than 100%.

Announced allocation percentages must be rounded to the nearest 1%.

Announced allocation percentages must be reviewed, and revised percentages announced within 2 weeks after a major inflow occurs. A major inflow is defined as one that would result in:

- The announced allocation percentage increasing to 100%; or
- The announced allocation percentage increasing by 5% or more.

If the announced allocation percentage is less than 100%, the announced allocation percentage should be reviewed at intervals not greater than 3 months.

The ROL holder should advise water users of forecast announced allocations, including details of the parameters used in determining the forecast values. The criteria for forecasting announced allocations, including the timing, frequency and level of accuracy must take into account water user requirements, and be made available to water users.

## 1.2 Calculation of announced allocation percentages

### 1.2.1 Medium priority water allocations

The initial announced allocation and any revised announced allocation for medium priority water allocations (AAm) must be determined from the following relationship.

$$AAm * MPA = (UV + IN - HPA - RE - TOL + USE - VIWY) * 100$$

The parameters used in this relationship are defined in Section 5.

For a medium priority water allocation that has been converted from a high priority water allocation, medium priority announced allocation must not apply to the medium priority allocation for the water year in which the change to a medium priority water allocation was registered.

### **1.2.2 High priority water allocations**

The announced allocation percentage for high priority water allocations (AAh) must be 100% if the announced allocation determined for medium priority water allocations is greater than zero.

If the announced allocation percentage for medium priority water allocations is zero, the amount of water that may be taken by high priority water allocations may be subject to the critical water supply water sharing rules in Section 2.1.

For a high priority water allocation that has been converted from a medium priority water allocation, high priority announced allocation must not apply to the high priority allocation for the water year in which the change to a high priority water allocation was registered.

## **Critical water supply water sharing rules**

### **2.1 High priority water allocations**

If the announced allocation percentage for medium priority water allocations is zero, the amount of water that may be taken by high priority water allocations must be determined from the following relationship.

$$AAh * HPA = (UV + IN - TOL + USE - VIWY) * 100$$

The parameters used in this relationship are defined in Section 5.

## **3 Transfer of water between water years**

The ROL holder may develop and apply scheme practices for carry over and forward draw of water entitlements in accordance with the principles and rules in this section.

### **3.1 Principles for transfer of water between water years**

The ROL holder must have regard to the following principles in developing and applying scheme practices for carry over and forward draw of water entitlements.

Carry over and forward draw practices must not have an adverse impact on the objectives of the Water Resource Plan (WRP).

Entitlements must not be:

- Carried over from the current water year to any future year; other than the next water year; or
- Brought forward from a future water year to the current water year, other than from the

next water year.

The volume of an individual water entitlement carried over to the next water year must not exceed the unused portion of the entitlement at the end of the water year.

The volume of individual water allocation brought forward to the current water year must not exceed the announced allocation volume for the allocation at the start of the next water year.

The ROL holder must apply such loss factors to carry over water as necessary to avoid:

- Adverse impacts on other water entitlement holders; and
- Adverse impacts on the objectives of the WRP.

The ROL holder must consider the effects of storage overflow on the volume of carry over.

### 3.2 Rules for transfer of water between water years

The following rules apply for the transfer of water between water years.

The total volume permitted to be brought forward to a water year must not exceed the volume given in Table 1.

**Table 1: Maximum water allocation volume that may be brought forward to a water year**

Storage level of Fairbairn Dam at 1 July in next water year (m AHD)	Maximum total water allocation volume permitted to be brought forward to a water year (ML)
Greater than EL 197 m (460,000 ML)	40,000
Between EL 197 m & EL 193 m (184,000 ML)	25,000
Below EL 193 m	5,000

The total volume permitted to be carried over to a water year must not exceed the volume given in Table 2.

**Table 2: Maximum water allocation volume that may be carried over to a water year**

Storage level of Fairbairn Dam at 1 July (m AHD)	Maximum total water allocation volume permitted to be carried over to a water year (ML)
Greater than EL 197 m (460,000 ML)	150,000
Between EL 197 m & EL 193 m (184,000 ML)	75,000
Below EL 193 m	25,000

The ROL holder must not supply any water carried over from the previous water year that was unused at the time an overflow of Fairbairn Dam commences.

### 3.3 End of water year minor adjustments

As an administrative arrangement to account for the timing of the end of water year metered use reading and for the operational convenience of water users, the ROL holder may, in addition to any carry over or forward draw permitted under Section 3.1 and Section 3.2, make minor carry over and forward draw adjustments to entitlements. For an individual, the adjustments must not exceed 2% of the individual entitlement at the end of the water year for which the meter reading applies, or 10 ML whichever is the lesser.

## **4 Seasonal water assignment rules**

Under Section 146B of the Water Act the holder of a water allocation may enter into an arrangement for a seasonal assignment in relation to the allocation. However the allocation holder may enter into the arrangement only with the consent of the ROL holder. The ROL holder may give consent only if the assignment is allowed under the seasonal water assignment rules in the ROP.

The ROL holder is required to report (refer Section 3.2.1 of Attachment 4.2G) on trends in seasonal assignment and evaluate whether seasonal assignment practices are impacting on supply for individual water users or groups of water users or impacting on the objectives of the WRP.

Chapter 8 of the ROP allows the chief executive to initiate changes to the seasonal assignment rules if considered necessary to protect the objectives of the WRP.

### **4.1 Principles for seasonal water assignment**

The ROL holder must have regard to the following principles in developing scheme practices and for making decisions for consent of seasonal water assignment arrangements.

The effects of an individual seasonal assignment and the cumulative effects of successive or repeated seasonal assignments must not:

- Impact adversely on the WRP objectives;
- Impact adversely on the availability of water to other water users in any part of the scheme; or
- Subject waterholes to an increased potential for environmental harm.

The water under seasonal assignment may only be supplied from within the Nogoia Mackenzie Water Supply Scheme area.

### **4.2 Rules for seasonal water assignment**

The following rules apply in developing scheme practices and for making decisions for consent of seasonal water assignment arrangements.

Water supplied under a seasonal water assignment may be used for any purpose.

Seasonal assignment of a water allocation with a specified purpose of ‘distribution loss’ is not permitted.

A seasonal water assignment must not result in the seasonal water assignment value lying outside the seasonal water assignment limits in Table 3. The seasonal water assignment value for a zone grouping in Table 3 is the total nominal volume for all medium and high priority water allocations in that zone grouping at the start of the water year, adjusted by the net volume of water seasonally assigned into or out of that zone grouping to date since the start of the water year.

**Table 3: Seasonal water assignment limits**

Seasonal water assignment limits (ML)	Mackenzie N, Mackenzie M, Mackenzie L, Mackenzie K & Mackenzie J	Mackenzie I & Mackenzie H	Mackenzie G, Mackenzie F & Mackenzie E	Mackenzie D, Mackenzie C & Mackenzie B
Minimum volume		12,000	10,000	5,182
Maximum volume		46,000		18,882

## 5 Definition of parameters

### **AAM = Announced allocation percentage medium priority**

The percentage of the nominal volume for a medium priority water allocation that may be supplied for the current water year.

### **AAH = Announced allocation percentage high priority**

The percentage of the nominal volume for a high priority water allocation that may be supplied for the current water year.

### **MPA = Medium priority water allocations**

The volume of medium priority water allocations in the scheme.

### **HPA = High priority water allocations**

The volume of high priority water allocations in the scheme.

### **USE = Volume of water taken**

The volume of water taken in the current water year up to the time of the assessment of the announced allocation (excluding any water taken in the current water year that had been carried over).

### **UV = Useable volume**

UV is determined by summing the useable volume of each of the storages included in the assessment of the announced allocation, as per the following equations:

$$UV = \text{sum}(UV_{\text{storage}})$$

$$UV_{\text{storage}} = (CV - DSV - SL)$$

$$UV_{\text{storage}} = 0 \text{ if } (CV - DSV - SL) \text{ is less than zero}$$

Where:

UV<sub>storage</sub> is the useable volume of each storage.

CV is the current volume of the storage.

DSV is the dead storage volume of the storage.  
SL is the storage losses.

For the purpose of the assessment of the announced allocations, the volumes of Fairbairn Dam, Bedford Weir, Bingley Weir and Tartrus Weir are included in the calculation. The volume of Selma Weir is ignored in the calculation.

**SL = Storage losses**

SL is the projected storage losses from the storages for the remainder of the water year (note: storage losses include lake evaporation plus seepage, minus direct rainfall onto the storage).

The storage loss depths to be used for each storage are given in Table 4. The value for the current month is multiplied by the current surface area of the storage. The storage loss for each storage is determined and then summed to give the total storage loss.

**Table 4: Projected storage losses for each storage**

Month in which announced allocation is calculated	Storage loss for Fairbairn Dam (mm)	Storage loss for Bedford Weir, Bingegang Weir and Tartrus Weir (mm)
July	1,660	1,770
August	1,580	1,680
September	1,470	1,570
October	1,340	1,420
November	1,170	1,240
December	990	1,050
January	770	830
February	580	620
March	410	440
April	260	290
May	160	170
June	75	85

**IN = Inflow**

IN is the allowance for inflows used in the resource assessment. The inflows to be used for this system are given in Table 5. The number used in the equation for inflows (IN) is the value in the table for the month in which the calculation is undertaken.

**Table 5: Inflow allowances**

Month in which announced allocation is calculated	Inflow (ML)
July	0
August	0
September	0
October	0
November	0
December	0
January	0
February	0
March	0
April	0
May	0
June	0

**RE = Reserve**

RE is the storage volume set aside for supply and associated losses in future water years. RE must be determined using the following relationship:

$$\mathbf{RE = (RES * HPA)/44,398}$$

Where RES is the reserve volume for the current month at the time of the calculation given in Table 6.

**Table 6: Reserve volumes**

Month in which announced allocation is calculated	Reserve (ML)
July	54,700
August	54,700
September	60,400
October	66,400
November	72,700
December	79,200
January	86,000
February	93,100
March	100,300
April	100,300
May	107,800
June	115,400

**TOL = Transmission and operational losses**

TOL is an allowance for river transmission and operational losses expected to occur in running the system from the date of the announced allocation assessment to the end of the current water year. TOL varies with the announced allocation for medium priority water allocations.

The transmission and operational loss allowance to be used is given in Table 7. TOL is to be linearly interpolated for intermediate values of medium priority announced allocation.

**Table 7: Transmission and operational losses**

Month in which announced allocation is calculated	Transmission and operational loss allowance (ML)	
	At AAm = 0%	At AAm = 100%
July	9,020 *F <sub>0</sub>	25,880 *F <sub>100</sub>
August	8,250 *F <sub>0</sub>	24,610 *F <sub>100</sub>
September	7,490 *F <sub>0</sub>	23,340 *F <sub>100</sub>
October	6,750 *F <sub>0</sub>	21,250 *F <sub>100</sub>
November	5,980 *F <sub>0</sub>	17,450 *F <sub>100</sub>
December	5,240 *F <sub>0</sub>	16,030 *F <sub>100</sub>
January	4,470 *F <sub>0</sub>	12,400 *F <sub>100</sub>
February	3,710 *F <sub>0</sub>	7,920 *F <sub>100</sub>
March	3,020 *F <sub>0</sub>	4,700 *F <sub>100</sub>
April	2,250 *F <sub>0</sub>	3,600 *F <sub>100</sub>
May	1,510 *F <sub>0</sub>	2,520 *F <sub>100</sub>
June	740 *F <sub>0</sub>	1,420 *F <sub>100</sub>

Where:

$$F_0 = \text{HPA}/44,398$$

$$F_{100} = (\text{HPA} + \text{MPA})/235,323$$

**VIWY = Net total volume of unused water allocation moved into current water year**

VIWY is the net total volume of unused water allocation that is moved into a water year from the previous water year, taking into account:

- The volume of water carried over to the current water year from the previous water year;
- The volume of water brought forward from the current water year to the previous water year; and
- The volume of water carried over to the current water year that had been supplied in the current water year as at the date of the assessment of the announced allocation.

# Attachment 4.2G

## Nogoa Mackenzie Water Supply Scheme Monitoring program

### 1 Water quantity

#### 1.1 Height and stream flow

The Resource Operations Licence (ROL) holder must record height and flow data in accordance with Table 1.

**Table 1: Locations in the Nogoa and Mackenzie rivers where height and flow data is required**

Location	Height data	Flow data
Fairbairn Dam inflow		✓
Fairbairn Dam storage	✓	
Fairbairn Dam outflow		✓
Bedford Weir inflow		✓
Bedford Weir storage	✓	
Bedford Weir outflow		✓
Bingegang Weir inflow		✓
Bingegang Weir storage	✓	
Bingegang Weir outflow		✓
Tartrus Weir inflow		✓
Tartrus Weir storage	✓	
Tartrus Weir outflow		✓

It is preferred that continuous time series data be collected. However, the chief executive may approve the collection of data in a format and standard other than for continuous time series data.

The methodology for determining height and flow data, including data format and standard, must be approved by the chief executive.

#### 1.1a Operating level of storages

The ROL holder must record for Fairbairn Dam, Bedford Weir, Bingegang Weir and Tartrus Weir:

- The daily storage height; and
- The daily storage outflow.

The ROL holder must record for Selma Weir:

- The daily storage height when Selma Weir is below nominal operating level.

For the purposes of this section:

- The methodology for determining the daily storage height and daily storage outflow must be approved by the chief executive; and
- The data must be real time information upon which operational decisions were based not data that has subsequently changed for example through a verification process.

---

**1.1b Stream flow for the purpose of first post-winter flow management strategies**

The ROL holder must record for each storage where a first post-winter flow management strategy applies under Section 3 of Attachment 4.2E:

- The storage inflow;
- The storage height; and
- The storage outflow.

For the purposes of this section:

- The methodology for determining the storage inflow, storage height and storage outflow must be approved by the chief executive;
- The storage inflow, storage height and storage outflow are only required to be recorded for the duration of the implementation of the first post-winter flow management strategy; and
- The data must be real time information upon which operational decisions for the implementation of the strategy were based not data that has subsequently changed for example through a verification process.

**1.1c Stream flow for the purpose of seasonal base flow management strategies**

The ROL holder must record for each storage where a seasonal base flow management strategy applies under Section 4 of Attachment 4.2E:

- The daily storage inflow volume;
- The daily storage inflow volume adopted for the purpose of determining passing flow requirements under the rules for the seasonal base flow management strategy. That is, the inflow volume after any adjustment to account for water released from an upstream storage for maintaining storage heights or to supply water users, in accordance with the seasonal base flow rules;
- The daily storage height; and
- The daily storage outflow.

For the purposes of this section:

- The methodology for determining the daily storage inflow volume, daily storage inflow volume adopted for the purpose of determining passing flow requirements, daily storage height and daily storage outflow must be approved by the chief executive; and
- The data must be real time information upon which operational decisions for the implementation of the strategy were based not data that has subsequently changed for example through a verification process.

**1.2 Releases from storages**

The ROL holder must record details of the basis for each release decision for each storage under the rules for releases of water from storages given in Section 2 of Attachment 4.2E, including:

- The general rules for releases including those specified in Section 2.4 of Attachment 4.2E;
- The release rate rules;
- The first post-winter flow and seasonal base flow management strategies; and

- The quality of water released from storages.

The ROL holder must record the time, date and release rate each time a release rate is changed for each storage. In addition, for storages with a multi-level inlet, the ROL holder must record the level from which the release is made and the basis of the decision for determining that level.

The ROL holder must record the daily volume released (through the outlet/s) from each storage.

The ROL holder must record daily volumes of supplemented water released to Retreat Creek under the rules for use of unsupplemented watercourses for delivery of supplemented water given in Section 8 of Attachment 4.2E.

The ROL holder must provide a proposed methodology for accounting for the supply of water orders under Section 2.4 of Attachment 4.2E to the chief executive within 40 business days of the commencement of the plan amendment (revision 2) for approval.

### **1.3 Announced allocations**

The ROL holder must record details of announced allocation determinations, referred to in Section 1 and Section 2 of Attachment 4.2F, including:

- The date and value for announced allocations, including the initial and any interim announced allocations; and
- The parameters applied for each announced allocation determination, including the initial and any interim announced allocations.

### **1.4 Transfer of water between water years**

The ROL holder must record details of the transfer of water between water years referred to in Section 3 of Attachment 4.2F, including:

- Scheme practices applied for carry over and forward draw of water entitlements;
- The basis of each decision to adjust the amount of water an individual may be supplied in a water year and the volume of the adjustment;
- The basis of each decision to approve a carry over or forward draw for each individual water user;
- The volume of water carried over from a water year to the next water year; and
- The volume of water brought forward from the next water year to a water year by priority group.

### **1.5 Seasonal water assignment**

The ROL holder must record details of individual seasonal water assignment arrangements.

### **1.6 Water taken by water users**

The ROL holder must record the volume of water taken by water users as follows:

- For each individual water user specified for each zone:
  - The total volume of supplemented water taken each quarter;
  - The total volume of supplemented water entitled to be taken at any time;

- 
- The basis for determining the total volume of supplemented water entitled to be taken at any time, including any adjustments for approved seasonal water assignments and transfers into or out of the water years;
  - The total volume of metered water taken as ‘riparian entitlement water’; and
  - The zone.

Note: Water taken under a water allocation with purpose ‘distribution loss’ should be recorded as an individual water user.

The ROL holder must record the daily volumes of supplemented water supplied to each water user from Retreat Creek and the associated meter readings.

### **1.7 Water diversions**

The ROL holder must record the daily volume of water diverted to:

- Selma channel system;
- Weemah channel system; and
- Blackwater pipeline.

The methodology for determining the volume must be approved by the chief executive.

### **1.8 Waterholes**

The ROL holder must:

- Establish a unique identifier for any waterhole from which supplemented water is taken that is drawn down more than 0.6 metres below cease to flow level; and
- Record the water level in the waterhole each day that supplemented water is taken from the waterhole and the water level is more than 0.6 metres below the cease to flow level.

## **2 Impact of storage operation on aquatic ecosystems**

The ROL holder must undertake the following to establish any impacts on aquatic ecosystems that are potentially related to the operation of storages.

### **Section 2.1 Bank condition**

The ROL holder must inspect banks for evidence of collapse and/or erosion within the ponded area and downstream of storages following instances of rapid water level changes or large flows through storages, or other occasions when collapse and/or erosion of banks may be likely. The distance downstream is the distance of influence of storage operations.

Any instances of bank slumping or erosion observed must be investigated to determine if the instability was associated with the nature or operation of the infrastructure.

## **2.2 Water Quality**

The ROL holder must monitor water quality in relation to relevant infrastructure in accordance with the department's Water Monitoring Data Collection Standard.

## **2.3 This section not required**

## **2.4 Fish stranding**

The ROL holder must investigate instances of fish stranding downstream of storages to determine if the fish stranding is associated with operation of infrastructure. The distance downstream of storages is the distance of influence of storage operations.

## **3 Reporting**

There are four levels of reporting for ROL holders:

- Quarterly report for the previous quarter;
- Annual report for the previous water year;
- Operational reports; and
- Emergency reports.

### **3.1 Quarterly report**

The ROL holder must transfer the following data to the chief executive:

- Water quantity all records referred to in Sections 1.1a and 1.1c;
- Release from storages where applicable, the level from which releases were made referred to in Section 1.2;
- Waterholes all records referred to in Section 1.8;
- A summary of bank condition monitoring and incidences of slumping referred to in Section 2.1;
- Water quality all records referred to in Section 2.2; and
- Seasonal water assignments all records referred to in section 1.5.

### **3.2 Annual report**

The annual report must include, but not be limited to, discussion and recommendations with regard to monitoring and assessment for the previous water year as follows.

#### **3.2.1 Water monitoring**

A summary of the implementation of the rules for releases from storages, other than for first post-winter flow and seasonal base flow management and quality of water released from storages.

A summary of the implementation of the first post-winter flow and seasonal base flow management strategies for each applicable storage, including:

- Overview of strategy implementation, including the basis of decisions; and
- An evaluation of the first post-winter flow and seasonal base flow management arrangements and outcomes.

A summary of the implementation of the quality of water released from storages rules for

---

---

each applicable storage, including:

- Overview of rule implementation;
- Basis of the decisions on the level from which to make releases; and
- Periods of release from each offtake level.

A summary of waterhole management including:

- Overview of waterhole management implementation; and
- Periods when the water level in a waterhole was more than 0.6 metres below its cease to flow level for more than 2 consecutive days and supplemented water was being taken.

A summary of announced allocation determinations, including:

- An evaluation of the announced allocation procedures and outcomes; and
- The date and value for each announced allocation.

A summary of the critical water supply water sharing rules, including:

- An evaluation of the rules and outcomes.

A summary of the transfer of water between water years including:

- An evaluation of the rules and outcomes;
- The total volume of water carried over to the water year from the previous water year;
- The total volume of water carried over from the water year to the next water year;
- The total volume of water brought forward by priority group to the water year from the next water year; and
- The total volume of water brought forward by priority group from the water year to the previous water year.

A summary of the volumes of water taken by water users, specified by zone, including:

- The total volume of supplemented water taken;
- The total volume of supplemented water entitled to be taken;
- The basis for determining the total volume of supplemented water entitled to be taken, including any adjustments for approved seasonal water assignments and transfers into or out of the water years;
- The announced allocation volume at the end of the water year; and
- The total volume of metered water taken as 'riparian entitlement water'.

A summary of seasonal water assignment arrangements, including:

- An evaluation of the seasonal water assignment rules and outcomes, including:
  - An evaluation of any circumstances of supply difficulties when the supply difficulties were linked to seasonal water assignment practices; and
  - Identification of and reporting on any trends in seasonal water assignment;
- The total number of seasonal water assignment arrangements;
- The total volume of water seasonally assigned;
- The maximum seasonal water assignment value for each zone grouping in Table 3 of Attachment 4.2F; and
- The minimum seasonal water assignment value for each zone grouping in Table 3 of Attachment 4.2F.

---

Details of changes to storages or their operation that may have an impact on the implementation of the ROP.

Details of new monitoring devices such as equipment to measure stream flow.

### **3.2.2 Impact of storage operation on aquatic ecosystems**

#### **Bank condition and fish stranding**

A summary of bank condition and fish stranding monitoring including:

- Results of investigations of bank slumping or erosion identified in ponded areas and downstream of storages;
- Results of any investigations of fish stranding downstream of storages; and
- Changes to operation of storages to reduce instances of bank slumping, erosion or fish stranding.

#### **Water quality**

Discussion and assessment of the following water quality issues:

- Thermal and chemical stratification in each storage;
- Water quality in each storage;
- Contribution of the storage and its management to the quality of water released;
- Cumulative effect of successive storages on water quality; and
- Cyanobacteria population changes in response to stratification in each storage.

### **3.3 Operational reports**

The ROL holder must notify the chief executive within 1 business day of becoming aware of the following operational incidents:

- Noncompliance by the ROL holder with the rules given in the ROP;
- A decision relating to each announced allocation; and
- Instances of fish stranding downstream of a storage.

The ROL holder must provide an operational report to the chief executive for the following operational incidents:

- Noncompliance with the rules in the ROP;
- Instances where the amount of water taken by users being supplied with supplemented water from Retreat Creek in any day exceeds the amount of supplemented water released to Retreat Creek on that day; and
- Instances of fish stranding downstream of a storage.

The report must provide details of the incident, conditions under which the incident occurred and any responses or activities carried out as a result of the incident.

The ROL holder must provide an operational report to the chief executive within 5 business days after a decision relating to each announced allocation. The report should include the parameters applied referred to in Section 1.3.

The ROL holder must provide a report to the chief executive within 5 business days after

implementation of a first post-winter flow management strategy ends. The report should include:

- Storage inflow, storage height and storage outflow records referred to in Section 1.1b.

### **3.4 Emergency report**

An emergency for the purpose of this ROP includes an occurrence, which by the nature of its severity, extent or timing might be regarded as an emergency (for example, contamination of water supply, structural damage to infrastructure or a danger to human health).

For any emergency, the ROL holder must:

- Notify the chief executive immediately; and
- Provide a report to the chief executive on the emergency including details of the emergency, conditions under which the emergency occurred, any responses or activities carried out as a result of the emergency and any impacts on the ROP.

# Attachment 4.2H

## Nogoa Mackenzie Water Supply Scheme

### Water allocation change rules

#### 1 Permitted changes

The permitted changes apply only to water allocations with purpose ‘agriculture’ or ‘any’.

Application for the following changes to a water allocation will be approved. On approval, a change certificate will be issued by the chief executive, which may be lodged with the registrar of water allocations.

##### 1.1 Location

Subject to Section 1.1.1, a change to the location of a water allocation from one of the following zones to any other of those zones:

- Mackenzie B;
- Mackenzie C;
- Mackenzie D;
- Mackenzie E;
- Mackenzie F;
- Mackenzie G;
- Mackenzie H;
- Mackenzie I;
- Mackenzie J;
- Mackenzie K;
- Mackenzie L;
- Mackenzie M; or
- Mackenzie N.

For the permitted changes to the location of a water allocation given in this section, conversion factors do not apply to the volume for the water allocation – that is, the volume for the water allocation will be the same before and after the change of location. However, this does not preclude consideration of conversion factors to enable changes under Section 3.

##### 1.1.1 Limitations on change of location

A proposed change is not a permitted change if the proposed change would result in a distribution of medium and high priority water allocations not provided for in Tables 1, 2 and 3.

##### 1.2 Purpose

A change to the purpose of a water allocation from ‘any’ to ‘agriculture’ or from ‘agriculture’ to ‘any’.

### 1.3 Amalgamation or subdivision

A change to subdivide a water allocation provided:

- The sum of the nominal volumes of the new water allocations is equal to the nominal volume of the water allocation that is being subdivided; and
- The location and priority group of the new water allocations is the same as that of the water allocation that is being subdivided.

A change to amalgamate water allocations provided:

- The nominal volume of the new water allocation is equal to the sum of the nominal volumes of the water allocations that are being amalgamated;
- The location and priority group of the water allocations that are being amalgamated are the same; and
- The location and priority group for the new water allocation is the same as that of the water allocations that are being amalgamated.

### 1.4 Priority

A change to the priority group of a water allocation from medium to high, provided:

- The conversion rate is 3.0 ML of medium-priority water allocation converts to 1 ML of high-priority water allocation; and
- The storage level in Fairbairn Dam is not less than EL 199.5 m AHD (702,000 ML) on the date the application for the change is received by the chief executive.

A change to the priority group of a water allocation from high to medium priority, provided:

- The conversion rate is 1 ML of high-priority water allocation converts to 3 ML of medium-priority water allocation.

#### 1.4.1 Limitations on change of priority

A proposed change is not a permitted change if the proposed change would result in a distribution of medium- and high-priority water allocations not provided for in Tables 1, 2 and 3.

**Table 1: Permitted distributions of high-priority water allocations in zones Mackenzie N, M, L, K, J, I, H, G, F, E, D, C and B**

Volume of high priority water allocation (ML)	Mackenzie N, Mackenzie M, Mackenzie L, Mackenzie K & Mackenzie J	Mackenzie I & Mackenzie H	Mackenzie G, Mackenzie F & Mackenzie E	Mackenzie D, Mackenzie C & Mackenzie B
Minimum volume		12,000	10,000	
Maximum volume		56,000		700

**Table 2: Permitted distributions of medium-priority water allocations in zones Mackenzie N, M, L, K, J, I, H, G, F, E, D, C and B**

Volume of water allocation (ML)	Mackenzie N, Mackenzie M, Mackenzie L, Mackenzie K & Mackenzie J	Mackenzie I & Mackenzie H	Mackenzie G, Mackenzie F & Mackenzie E	Mackenzie D, Mackenzie C & Mackenzie B
Minimum volume				5,182
Maximum volume		18,000		18,182
		191,000		

**Table 3: Permitted distributions of water allocations in zones Mackenzie N, M, L, K, J, I, H, G, F, E, D, C and B**

Volume of water allocation (ML)	Mackenzie N, Mackenzie M, Mackenzie L, Mackenzie K & Mackenzie J	Mackenzie I & Mackenzie H	Mackenzie G, Mackenzie F & Mackenzie E	Mackenzie D, Mackenzie C & Mackenzie B
Minimum volume				
Maximum volume		46,000		

## 2 Prohibited changes

The following changes are prohibited changes:

### 2.1 Location

A change to a location that is not within the extent of the Dawson Valley, Nogoia Mackenzie, Lower Fitzroy or Fitzroy Barrage water supply schemes.

### 2.2 Priority group

A change to a priority group that is not medium or high.

### 2.3 Purpose

A change to a purpose that is not 'agriculture' or 'any'.

### 2.4 Volume

A change to the volume that is not a consequence of a change to another attribute of a water allocation.

### 2.5 Other

A change that requires an amendment to this ROP, other than an amendment provided for in Chapter 8.

### **3 Application for change under Section 130 of the Water Act**

If a water allocation holder wishes to apply for a change to a water allocation that is not permitted under Section 1, and not prohibited under Section 2, an application may be made under Section 130 of the Water Act for the change.

The chief executive will deal with applications made under Section 130 of the Water Act, in accordance with the Water Act. That process is as follows:

- Notice of the application is published in local newspapers. The notice includes information about where the application can be inspected and invites submissions from the public on the application;
- The chief executive determines if the application should be approved having regard to the potential impact on a range of interests including other entitlement holders and aquatic ecosystems;
- If the chief executive approves the application, the chief executive will issue a change certificate that may be lodged with the registrar of water allocations; and
- If the chief executive refuses the application, the Water Act provides for an appeal process.

#### **3.1 Purpose**

Any application to change the purpose of a water allocation from 'distribution loss' to 'any' must be supported by information to substantiate to the satisfaction of the chief executive an efficiency gain within the associated channel system. An application may be made for efficiency gains made since the issue of the interim resource operations licence for the Nogo Mackenzie Water Supply Scheme in November 2000.

#### **4 Registration of change**

If an application to change a water allocation is approved, the chief executive will issue a change certificate. The water allocation holder may lodge the change certificate with the registrar of water allocations who will change the water allocation on the water allocation register.

However, the registrar will not register the change until a supply contract has been entered into between the water allocation holder and the Resource Operations Licence (ROL) holder for supply of the changed water allocation.

# Attachment 4.2I

## Nogoa Mackenzie Water Supply Scheme

### Amending critical water supply management arrangements

#### 1 Critical water supply management arrangements

##### 1.2 Introduction

The Resource Operations Plan (ROP) rules for infrastructure operation and environmental management (refer Attachment 4.2E) and for water sharing (refer Attachment 4.2F) include arrangements for dealing with periods of low water availability. These arrangements are referred to as the critical water supply management arrangements.

The critical water supply management arrangements initially specified in the ROP are based on broad-scale basin-wide hydrologic modelling. These initial arrangements may need to be refined and further developed to ensure the arrangements appropriately deal with local issues and circumstances particular to the Nogoa Mackenzie Water Supply Scheme.

Over time the arrangements can also be amended to allow adaptation to changing circumstances and refinement through improved knowledge about the operation of the system at times of low water supply.

For example, the initial arrangements for sharing the available supplies may warrant ongoing development to secure supplies for essential water needs.

Variations to the rules associated with the minimum operating levels for storages and to the waterhole drawdown limits given in Attachment 4.2E may also be considered to accommodate local water user and environmental needs under particular circumstances.

##### 1.2 Criteria for critical water supply management arrangements

Critical water supply management arrangements must have regard to the following:

- Provision of water for essential water needs must have first priority;
- The objectives of the Water Resource Plan;
- The effects on water allocation security performance;
- The effects on natural ecosystems and the physical integrity of the watercourse; and
- The public interest.

For the purpose of the critical water supply management arrangements, essential water needs must include that part of a town water supply required for essential services including drinking water and sanitation but excluding lawns and gardens. The Resource Operations Licence (ROL) holder in conjunction with water allocation holders may establish additional essential purposes.

### **1.3 Initial review of the critical water supply management arrangements**

The ROL holder must undertake an initial review of the suitability of the critical water supply management arrangements. A report on the initial review must be provided to the chief executive within 12 months of the commencement of the ROP.

The initial review must include recommendations on whether amendments to the arrangements should be considered.

### **1.4 Proposals to amend the critical water supply management arrangements**

The ROL holder may submit a proposal to amend the critical water supply management arrangements at any time.

The chief executive may require the ROL holder to prepare a proposal to amend the critical water supply management arrangements at any time.

If the initial review of the critical water supply management arrangements under Section 1.3 indicates changes to the arrangements should be considered, the chief executive may require the ROL holder to prepare a proposal to amend the critical water supply management arrangements within a timeframe set by the chief executive.

A proposal to amend the critical water supply management arrangements must include:

- Proposed changes to the rules for infrastructure operation and environmental management (refer Attachment 4.2E) and for water sharing (refer Attachment 4.2F);
- An assessment of the effects of the proposal on natural ecosystems and the physical integrity of the watercourse and the proposed environmental monitoring requirements;
- Details of consultation with stakeholders including water users, local communities and environmental interests; and
- Any other information that will assist the chief executive to decide the proposal.

### **1.5 Amending the critical water supply management arrangements**

The chief executive may amend the rules for infrastructure operation and environmental management (refer Attachment 4.2E) and for water sharing (refer Attachment 4.2F) that apply during periods of low water availability. The chief executive will consider the following in deciding to amend the rules:

- Any proposal to amend the critical water supply management arrangements submitted by the ROL holder; and
- The criteria given in Section 1.2.

### **1.6 Evaluation of critical water supply management arrangements**

The ROL holder must annually evaluate the critical water supply management arrangements in regard to their suitability for periods of low water availability.

Any changes that occur after 13 November 2003, for example, transfers of a listed authorisation to another person, or from amalgamations or subdivisions of listed authorisations, will be dealt with through standard procedures established to register changes to the water allocation register

# Attachment 4.3B

## Lower Fitzroy Water Supply Scheme

### Rules for conversion to water allocations

#### 1 Locations where existing authorisations are being converted to water allocations

Existing authorisations for supplemented water are being converted to water allocations on:

- The Fitzroy River from the upstream limit of Eden Bann Weir to the upstream limit of the Fitzroy Barrage; and
- Sections of tributaries of the Fitzroy River that contain water ponded from natural waterholes or infrastructure within the above section of the Fitzroy River.

#### 2 Rules for conversion of existing authorisations to water allocations

The following rules apply for the conversion of existing authorisations to water allocations to establish the details required for the registration of supplemented water allocations.

##### 2.1 Location

The location from which water may be supplied under a water allocation is specified as a zone according to the position of the existing authorisation. Descriptions of the zones for the Fitzroy River are given in Attachment 2.3.

##### 2.2 Purpose

The purpose for which water may be taken under a water allocation is specified as 'agriculture', 'distribution loss' or 'any'. 'Agriculture' is the nominated purpose for those existing authorisations that are primarily used for agricultural purposes. 'Distribution loss' is the nominated purpose for water allocations for distribution losses associated with the Stanwell Pipeline. 'Any' is the nominated purpose for all other uses of water.

##### 2.3 Volume

For an authorisation that states a volume, the nominal volume for a water allocation is the volume stated on the existing authorisation.

For an authorisation that states an area that may be irrigated, the nominal volume is calculated by multiplying the area (in hectares) stated on the existing authorisation by six (6).

##### 2.4 Priority group

The priority group for a water allocation converted from an existing authorisation to take supplemented water is medium priority, except where a product specification or other undertaking associated with the authorisation identifies the authorisation's water supply as being high priority water allocation.

# Attachment 4.3C

## Lower Fitzroy Water Supply Scheme

### Total volume of supplemented water allocations

Table 1: Total volume of supplemented water allocations at Resource Operations Plan approval

Zone	Medium priority water allocation (ML)	High priority water allocation (ML)
Fitzroy C	521	5
Fitzroy B	2,580	0
Fitzroy A	0	25,515
<b>Total</b>	<b>3,101</b>	<b>25,520</b>

## Attachment 4.3D

### Lower Fitzroy Water Supply Scheme Infrastructure details

#### Storage: Eden Bann Weir – Fitzroy River AMTD 141.2 km

<b>Description of water infrastructure</b>	
Main embankment	Mass concrete gravity weir
Full supply level	EL 14.5 m AHD
Fixed crest level	EL 14.5 m AHD
Saddle dam(s)	Nil
Fabridams	Nil
Gates	Nil
<b>Storage volume and surface area</b>	
Full supply volume	35,900 ML
Dead storage volume	9,650 ML
Surface area/storage volume/elevation relationship	Department of Primary Industries (Water Resources) Drawing No's. A3-110383 and A3-110384
<b>Spillway arrangement</b>	
Description of works	Two level concrete spillway
Spillway level	High level crest EL 14.8 m AHD Low level crest EL 14.5 m AHD
Spillway width	High level crest: 180 metres on right abutment Low level crest: 90 metres on left abutment
Discharge characteristics	Not available
<b>River inlet/outlet works</b>	
Description of works	Inlet structure through 1200 mm by 1200 mm sluice gate to 1500 mm by 1500 mm box culvert.
Multi level inlet	Works can accommodate selective withdrawal
Cease to flow level	EL 7.25 metres AHD
Discharge characteristics	Water Resources Drawing No. A3-101635
<b>Fish transfer system</b>	
Description of works	Fishlock located near the left bank adjacent to the outlet works

# Attachment 4.3E

## Lower Fitzroy Water Supply Scheme Rules for infrastructure operation and environmental management

### 1 Operating levels of storages and waterholes

#### 1.1 Nominal operating level of Fitzroy Barrage

Releases must be made from Eden Bann Weir to maintain the water level in the Fitzroy Barrage at its nominal operating level, unless the water level in Eden Bann Weir is below its local supply level.

Fitzroy Barrage storage levels may vary above and below the nominal operating level due to practical limitations of estimating and making releases and for unforeseen circumstances.

The nominal operating level for the Fitzroy Barrage is EL 3.38 m AHD (75,000 ML).

#### 1.2 Local supply level of Eden Bann Weir

The local supply level and local supply area for Eden Bann Weir are given in Table 1.

**Table 1: Local supply level and local supply area for Eden Bann Weir**

Storage	Local supply level	Local supply area
Eden Bann Weir	EL 9.55 m AHD (11,280 ML)	Eden Bann Weir pond and downstream, but excluding Fitzroy Barrage pond

Releases must not be made from Eden Bann Weir to the Fitzroy Barrage when the water level in Eden Bann Weir is below its local supply level, except:

- If the water level in the Fitzroy Barrage is below EL -0.5 m AHD (27,950 ML), releases should be made from Eden Bann Weir to the Fitzroy Barrage, to the extent that it is practicable; and
- To supply water allocation holders located within Eden Bann Weir's local supply area. The local supply area for Eden Bann Weir at a particular time extends to the pond of the Fitzroy Barrage at that particular time.

- 
- 
- 
-

### 1.3 Minimum operating level of Eden Bann Weir and the Fitzroy Barrage

The minimum operating levels for Eden Bann Weir and the Fitzroy Barrage are given in Table 2.

**Table 2: Minimum operating level of storages**

Storage	Minimum operating level
Eden Bann Weir	EL 7.25 m AHD (4,800 ML)
Fitzroy Barrage	EL -1.2 m AHD (21,900 ML)

Water must not be released or supplied from Eden Bann Weir if the water level in Eden Bann Weir is below its minimum operating level, unless otherwise authorised by the chief executive.

### 1.4 Minimum level in waterholes

For a waterhole within the extent of the Lower Fitzroy Water Supply Scheme:

- Supplemented water should not be taken from a waterhole that is more than 0.5 metres below its cease to flow level; and
- The chief executive may authorise supplemented water to be supplied from a waterhole when the level is more than 0.5 metres below its cease to flow level.

## 2 Releases of water from storages

### 2.1 General rules

When determining releases from Eden Bann Weir, the Resource Operations Licence (ROL) holder must have regard to the following:

- Total volume of water ordered, and its distribution;
- The likely contribution of inflows from tributaries that could assist the supply of orders;
- The likely transmission and operating losses;
- The travel time for water delivery;
- The volume of releases required to maintain the nominal operating level in the Fitzroy Barrage and to maintain levels in waterholes;
- The volume of releases required to maintain the minimum operating level in the Fitzroy Barrage;
- The local supply level of Eden Bann Weir;
- The fishway management strategy; and
- The quality of water released from Eden Bann Weir.

The ROL holder may incorporate provisions in supply contracts for circumstances when the release capacity of Eden Bann Weir is insufficient to meet downstream demand.

### 2.2 Release rate rules

Water may be released from Eden Bann Weir at a rate up to the maximum discharge capacity of its outlet works.

Any reduction in the rate of a release must occur incrementally, such that the risk of fish stranding and bank slumping is minimised.

### **3 First post-winter flow management strategy**

#### **3.1 Lower Fitzroy first post-winter flow management strategy**

There is no first post-winter flow management strategy.

### **4 Seasonal base flow management strategy**

There is no seasonal base flow management strategy.

While no specific releases are required to be made by the ROL holder for the Lower Fitzroy Water Supply Scheme for seasonal base flows, seasonal base flows will be passed through Eden Bann Weir as a consequence of:

- The seasonal base flow management rules for the Fitzroy Barrage Water Supply Scheme which require the ROL holder for that scheme to pass seasonal base flows based on inflows to Eden Bann Weir; and
- The release rules for the Lower Fitzroy Water Supply Scheme which require the ROL holder for this scheme to maintain the water level in the Fitzroy Barrage by releases from Eden Bann Weir.

### **5 Fishway management strategy**

The ROL holder is authorised to operate the Eden Bann Weir fishlock when the level of the water in the weir is between EL 12.7 m AHD and EL 16.0 m AHD.

The ROL holder may operate the fishlock at other times provided the releases from the weir are no more than that required to:

- Supply water; and
- Maintain nominal operating levels in the Fitzroy Barrage.

### **6 Quality of water released from Eden Bann Weir**

The ROL holder must draw water from the level that optimises the quality of the water released (for example, dissolved oxygen concentration and the temperature in the release water optimised), to minimise the impact on the downstream water quality. If this level does not provide enough capacity for the required release, other levels must be used to give the required discharge.

### **7 Use of watercourses for distribution of water**

The ROL holder may use the following watercourses for the purposes of distribution of water:

- The Fitzroy River from the upstream limit of Eden Bann Weir to the upstream limit of the Fitzroy Barrage;
- The Fitzroy River from the upstream limit of the Fitzroy Barrage to the Fitzroy Barrage; and
- Sections of tributaries of the Fitzroy River that contain water from natural waterholes and infrastructure within the above sections of the Fitzroy River.

The ROL holder must not divert water to any watercourse other than those given above for distribution of water.

## **8 Riparian stock and domestic use**

Under Section 20(3) of the Water Act, an owner of land adjoining a watercourse, lake or spring may take water for domestic purposes and watering stock that would be normally depastured on the land without a water entitlement. In this section this is referred to as 'riparian entitlement water'.

This means that riparian entitlement water might also be taken through the same metered water facilities as supplemented water and some users might desire appropriate allowances be made for their riparian entitlement water use. The historical arrangements for accounting for individual riparian use taken through metered facilities will not apply following commencement of the ROP.

### **8.1 Rules for adjusting metered use for riparian entitlement water use**

This section provides arrangements to allow adjustments for riparian entitlement water metered use.

The ROL holder must enter into an arrangement with any water user who requests metered use adjustments for riparian entitlement water use taken through a metered facility. The ROL holder must supply details of the arrangements with each individual user to the chief executive within 5 business days of an agreement.

An arrangement must comply with the departmental guidelines for this purpose.

If the ROL holder and a water user are unable to reach agreement on an arrangement, the chief executive will decide the arrangement that will apply in that particular instance.

# Attachment 4.3F

## Lower Fitzroy Water Supply Scheme

### Water sharing rules

This attachment provides water sharing rules for:

- Announced allocations;
- Critical water supply;
- Transfer of water between water years; and
- Seasonal water assignment.

#### **1 Announced allocation**

##### **1.1 General rules**

The water year for the Lower Fitzroy Water Supply Scheme is from 1 July to 30 June in the following year.

##### **1.2 Calculation of announced allocation percentages**

###### **1.2.1 Medium priority water allocations**

The announced allocation percentage for medium priority water allocations must be 100%.

###### **1.2.2 High priority water allocations**

The announced allocation percentage for high priority water allocations must be 100%.

#### **2 Critical water supply water sharing rule**

##### **2.1 Critical water supply water sharing rules during the medium priority restriction period**

For the Lower Fitzroy and the Fitzroy Barrage water supply schemes, the announced allocation must be 100% for both medium and high priority water. This means that at times the total medium priority allocation cannot be supplied without increasing the risk to high priority supply security.

This risk during critical water supply periods is addressed by preventing the supply of medium priority entitlements when the Fitzroy Barrage is below specified levels. In addition, the maximum allowable distribution of supply of high priority entitlement will be constrained during those periods when medium priority supply is restricted.

### 2.1.1 Medium priority restriction rule

Medium priority water allocation supply through the Lower Fitzroy Water Supply Scheme must:

- Cease when the water level in the Fitzroy Barrage falls below EL 0.75 m AHD (40,500 ML); and
- Not recommence unless the water level in the Fitzroy Barrage has risen above EL 0.85 m AHD (41,600 ML).

A period when the water level in the Fitzroy Barrage has fallen below EL 0.75 m AHD and not re-risen to above EL 0.85 m AHD is a ‘medium priority restriction period’.

### 2.1.2 High priority water use during the medium priority restriction period

During a medium priority restriction period referred to in Section 2.1.1, the holder of a high priority water entitlement must not be supplied more than a specified maximum volume during a specified period as defined by the high priority demand pattern assigned to the entitlement. The high priority demand pattern for water allocations is referred to in Section 2.1.3.

An entitlement may also include a seasonal water assignment of a high priority allocation referred to in Section 4.

### 2.1.3 High priority demand pattern

The Resource Operations Licence (ROL) holder must assign to each high priority water allocation a ‘high priority demand pattern’.

The high priority demand pattern has effect only when a medium priority restriction period is in effect.

During a medium priority restriction period, the high priority demand pattern defines the maximum amount of water that may be supplied under a high priority water allocation for specified calendar periods (for example, on a specific date, or a specific week, or a specific month). Any specified period must not be greater than 1 month.

The combined total of the high priority demand patterns for high priority water allocations supplied by the Lower Fitzroy Water Supply Scheme must not exceed the limits in Table 1.

**Table 1: Maximum percentage of total high priority water allocation in Lower Fitzroy Water Supply Scheme that may be assigned to the specified period under the high priority demand pattern**

Period	Percentage of total high priority allocation
July to September	31
October to December	34
January to March	34
April to June	31

#### **2.1.4 Other restrictions**

During the medium priority restriction period, the ROL holder may implement further restrictions on the supply of high priority water, decided by the ROL holder in conjunction with high priority water allocation holders for the purpose of extending the period that water supplies are available, provided the objectives of the Water Resource Plan (WRP) are not compromised.

### **3 Transfer of water between water years**

The ROL holder may develop and apply scheme practices for forward draw of water entitlements in accordance with the principles and rules in this section.

#### **3.1 Principles for transfer of water between water years**

The ROL holder must have regard to the following principles in developing and applying scheme practices for forward draw of water entitlements.

Forward draw practices must not have an adverse impact on the objectives of the WRP.

Entitlements must not be:

- Carried over from the current water year to any future year, other than a minor carry over adjustment under Section 3.3; or
- Brought forward from a future water year to the current water year, other than from the next water year.

The volume of individual water allocation brought forward to the current water year must not exceed the announced allocation volume for the allocation at the start of the next water year.

#### **3.2 Rules for transfer of water between water years**

The following rule applies for the transfer of water between water years.

The total volume permitted to be brought forward to a water year must not exceed 2% of the total nominal volume.

#### **3.3 End of water year minor adjustments**

As an administrative arrangement to account for the timing of the end of water year metered use reading and for the operational convenience of water users, the ROL holder may, in addition to any forward draw permitted under Section 3.1 and Section 3.2, make minor carry over and forward draw adjustments to entitlements. For an individual, the adjustments must not exceed 2% of the individual entitlement at the end of the water year for which the meter reading applies, or 10 ML whichever is the lesser.

### **4 Seasonal water assignment rules**

Under Section 146B of the Water Act, the holder of a water allocation may enter into an arrangement for a seasonal assignment in relation to the allocation. However the allocation holder may enter into the arrangement only with the consent of the ROL holder. The ROL holder may give consent only if the assignment is allowed under the seasonal water assignment rules in the Resource Operations Plan (ROP).

High priority water supply during medium priority restriction periods (Refer to Section 2) must comply with specified high priority demand patterns. A seasonal water assignment of a high priority water allocation also requires an assigned demand pattern for the purposes of Section 2.

The ROL holder is required to report (refer Section 4.1.1 Attachment 4.3G) on trends in seasonal assignment and evaluate whether seasonal assignment practices are impacting on supply for individual water users or groups of water users or impacting on the objectives of the WRP.

Chapter 8 of the ROP allows the chief executive to initiate changes to the seasonal assignment rules if considered necessary to protect the objectives of the WRP.

#### **4.1 Principles for seasonal water assignment**

The ROL holder must have regard to the following principles in developing scheme practices and for making decisions for consent of seasonal water assignment arrangements.

The effects of an individual seasonal assignment and the cumulative effects of successive or repeated seasonal assignments must not:

- Impact adversely on the WRP objectives;
- Impact adversely on the availability of water to other water users in any part of the scheme; or
- Subject waterholes to an increased potential for environmental harm.

Water with a location zone Fitzroy A must continue to be supplied in zone Fitzroy A.

Water with a location of either Fitzroy B or Fitzroy C must continue to be supplied in either zone Fitzroy B or Fitzroy C.

#### **4.2 Rules for seasonal water assignment**

The following rules apply in developing scheme practices and for making decisions for consent of seasonal water assignment arrangements.

Water supplied under a seasonal water assignment may be used for any purpose.

Seasonal assignment of a water allocation with a specified purpose of ‘distribution loss’ is not permitted.

A high priority demand pattern must be assigned to a seasonal water assignment of a high priority water allocation, the ‘original entitlement’, for the purposes of Section 2. An adjusted high priority demand pattern must be assigned for the ‘original allocation’ to account for the seasonal assignment. The combined demand patterns for the resultant entitlements must not exceed the demand pattern for the original entitlement.

# Attachment 4.3G

## Lower Fitzroy Water Supply Scheme Monitoring program

### 1 Water quantity

#### 1.1 Height and stream flow

The Resource Operations Licence (ROL) holder must record height and flow data in accordance with Table 1.

**Table 1: Locations in the Fitzroy River where height and flow data is required**

Location	Height data	Flow data
Eden Bann Weir inflow		✓
Eden Bann Weir storage	✓	
Eden Bann Weir outflow		✓

It is preferred that continuous time series data be collected. However, the chief executive may approve the collection of data in a format and standard other than for continuous time series data.

The methodology for determining height and flow data, including data format and standard, must be approved by the chief executive.

#### 1.1a Operating level of storages

The ROL holder must record under Section 1 of Attachment 4.3E:

- The daily storage height for Eden Bann Weir and the Fitzroy Barrage; and
- The daily storage outflow for Eden Bann Weir.

For the purposes of this section:

- The methodology for determining the daily storage height and daily storage outflow must be approved by the chief executive; and
- The data must be real time information upon which operational decisions were based not data that has subsequently changed for example through a verification process.

#### 1.2 Releases from storages

The ROL holder must record details of the basis for each release decision for Eden Bann Weir under the rules for releases of water from storages given in Section 2 of Attachment 4.3E, including:

- The general rules for releases;
- The release rate rules;
- The fishway management strategy; and
- The quality of water released from Eden Bann Weir.

The ROL holder must record the time, date and release rate each time a release rate is

changed for Eden Bann Weir. In addition, the ROL holder must record the level from which the release is made and the basis of the decision for determining that level.

The ROL holder must record the daily volume released (through the outlet/s and fishway) from Eden Bann Weir.

### **1.3 Announced allocations**

The ROL holder must record details of announced allocation determinations, referred to in Section 1 of Attachment 4.3F.

### **1.4 Restrictions on the taking of medium priority water during the medium priority restriction period**

The ROL holder must record details of any restrictions on the taking of medium priority water referred to in Section 2.1.1 of Attachment 4.3F, including:

- The date of the restriction;
- The nature of the restriction; and
- The basis for the determination of the restriction.

### **1.5 Restrictions on the taking of high priority water during medium priority restriction period**

The ROL holder must record details of any restrictions on the taking of high priority water referred to in Section 2.1.2 and Section 2.1.3 of Attachment 4.3F, including:

- The date of the restriction;
- The nature of the restriction; and
- The basis for the determination of the restriction.

### **1.6 Transfer of water between water years**

The ROL holder must record details of the transfer of water between water years referred to in Section 3 of Attachment 4.3F, including:

- The basis of each decision to adjust the amount of water an individual may be supplied in a water year and the volume of the adjustment;
- The basis of each decision to approve a forward draw for each individual water user; and
- The volume of water brought forward from the next water year to a water year by priority group.

### **1.7 Seasonal water assignment**

The ROL holder must record details of individual seasonal water assignment arrangements, including assigned high priority demand patterns.

## 1.8 Water taken by water users

The ROL holder must record the volume of water taken by water users as follows:

- For each individual water user specified for each zone:
  - The total volume of supplemented water taken each quarter;
  - The total volume of supplemented water entitled to be taken at any time;
  - The basis for determining the total volume of supplemented water entitled to be taken at any time, including any adjustments for approved seasonal water assignments and transfers into or out of the water years;
  - The total volume of metered water taken as ‘riparian entitlement water’; and
  - The zone.

Note: Water taken under a water allocation with purpose ‘distribution loss’ should be recorded as an individual user.

## 1.9 Water diversions

The ROL holder must record the daily volume of water diverted to Stanwell pipeline.

The methodology for determining the volume must be approved by the chief executive.

## 1.10 Waterholes

The ROL holder must:

- Establish a unique identifier for any waterhole from which supplemented water is taken that is drawn down more than 0.6 metres below cease to flow level; and
- Record the water level in the waterhole each day that supplemented water is taken from the waterhole and the water level is more than 0.6 metres below the cease to flow level.

## 1.11 High priority demand pattern

The ROL holder must record details of individual high priority demand patterns, referred to in Section 2.1.3 of Attachment 4.3F.

## 2 Impact of storage operation on aquatic ecosystems

The ROL holder must undertake the following to establish any impacts on aquatic ecosystems that are potentially related to the operation of storages.

### Section 2.1 Bank condition

The ROL holder must inspect banks for evidence of collapse and/or erosion within the ponded area and downstream of Eden Bann Weir following instances of rapid water level changes or large flows through Eden Bann Weir, or other occasions when collapse and/or erosion of banks may be likely. The distance downstream is the distance of influence of storage operations.

Any instances of bank slumping or erosion observed must be investigated to determine if the instability was associated with the nature or operation of the infrastructure.

## **2.2 Water Quality**

The ROL holder must monitor water quality in relation to relevant infrastructure in accordance with the department's Water Monitoring Data Collection Standard.

## **2.3 This section not required**

## **2.4 Fish stranding**

The ROL holder must investigate instances of fish stranding downstream of storages to determine if the fish stranding is associated with operation of infrastructure. The distance downstream of storages is the distance of influence of storage operations.

## **3 Reporting**

There are four levels of reporting for ROL holders:

- Quarterly report for the previous quarter;
- Annual report for the previous water year;
- Operational reports; and
- Emergency reports.

### **3.1 Quarterly report**

The ROL holder must transfer the following data to the chief executive:

- Water quantity all records referred to in Section 1.1a;
- Release from storages where applicable, the level from which releases were made referred to in Section 1.2;
- Waterholes all records referred to in Section 1.10;
- A summary of bank condition monitoring and incidences of slumping referred to in Section 2.1;
- Water quality all records referred to in Section 2.2; and
- Seasonal water assignments all records referred to in section 1.7.

### **3.2 Annual report**

The annual report must include, but not be limited to, discussion and recommendations with regard to the monitoring results for the previous water year.

#### **3.2.1 Water monitoring**

A summary of the implementation of the rules for releases from storages, other than for fishway management and quality of water released from Eden Bann Weir.

A summary of the implementation of the fishway management strategy for Eden Bann Weir, including:

- Overview of strategy implementation;
- Periods of operation of the fishway; and
- Total period of operation of the fishway.

A summary of the implementation of the quality of water released from Eden Bann Weir rule, including:

- Overview of rule implementation;
- Basis of the decisions on the level from which to make releases; and
- Periods of release from each offtake level.

A summary of waterhole management including:

- Overview of waterhole management implementation; and
- Periods when the water level in a waterhole was more than 0.6 metres below its cease to flow level for more than 2 consecutive days and supplemented water was being taken.

A summary of announced allocation determinations, including:

- An evaluation of the announced allocation procedures and outcomes.

A summary of restrictions on the taking of medium priority water, including:

- An evaluation of the restriction arrangements and outcomes; and
- The date and nature of each restriction decision.

A summary of restrictions on the taking of high priority water, including:

- An evaluation of the restriction arrangements and outcomes; and
- The date and nature of each restriction decision.

A summary of the transfer of water between water years including:

- An evaluation of the rules and outcomes;
- The total volume of water brought forward by priority group to the water year from the next water year; and
- The total volume of water brought forward by priority group from the water year to the previous water year.

A summary of the volumes of water taken by water users, specified by zone, including:

- The total volume of supplemented water taken;
- The total volume of supplemented water entitled to be taken;
- The basis for determining the total volume of supplemented water entitled to be taken, including any adjustments for approved seasonal water assignments and transfers into or out of the water years;
- The announced allocation volume at the end of the water year;
- The total volume of supplemented water taken during a medium priority restriction period; and
- The total volume of metered water taken as 'riparian entitlement water'.

A summary of seasonal water assignment arrangements, including:

- An evaluation of the seasonal water assignment rules and outcomes, including:
  - An evaluation of any circumstances of supply difficulties when the supply difficulties were linked to seasonal assignment practices; and
  - Identification of and reporting on any trends in seasonal water assignment;
- The total number of seasonal water assignment arrangements; and
- The total volume of water seasonally assigned.

Details of changes to Eden Bann Weir or its operation that may have an impact on the

implementation of the ROP.

Details of new monitoring devices such as equipment to measure stream flow.

### **3.2.2 Impact of storage operation on aquatic ecosystems**

#### **Bank condition and fish stranding**

A summary of bank condition and fish stranding monitoring including:

- Results of investigations of bank slumping or erosion identified in the ponded area of and downstream of Eden Bann Weir;
- Results of any investigations of fish stranding downstream of Eden Bann Weir; and
- Changes to operation of storages to reduce instances of bank slumping, erosion or fish stranding.

#### **Water quality**

Discussion and assessment of the following water quality issues:

- Thermal and chemical stratification in Eden Bann Weir;
- Water quality in Eden Bann Weir;
- Contribution of the storage and its management to the quality of water released;
- Cumulative effect of successive storages on water quality; and
- Cyanobacteria population changes in response to stratification in Eden Bann Weir.

### **3.3 Operational reports**

The ROL holder must notify the chief executive within 1 business day of becoming aware of the following operational incidents:

- Noncompliance by the ROL holder with the rules given in the ROP;
- A decision relating to any restrictions on the taking of medium priority water;
- A decision relating to any restrictions on the taking of high priority water; and
- Instances of fish stranding downstream of Eden Bann Weir.

The ROL holder must provide an operational report to the chief executive for the following operational incidents:

- Noncompliance with the rules in the ROP; and
- Instances of fish stranding downstream of Eden Bann Weir.

The report must provide details of the incident, conditions under which the incident occurred and any responses or activities carried out as a result of the incident.

The ROL holder must provide a report to the chief executive within 5 business days of the start of the water year detailing the high priority demand patterns assigned to each high priority water allocation referred to in Section 2.1.3 of Attachment 4.3F. The report should include:

- Water allocation number;
- Holder of water allocation; and
- High priority demand pattern.

The ROL holder must provide a report to the chief executive within 5 business days of a change to the high priority demand pattern associated with a high priority water allocation, or the establishment of a new high priority water allocation. The report should include:

- Water allocation number;
- Holder of water allocation; and
- High priority demand pattern.

### **3.4 Emergency report**

An emergency for the purpose of this ROP includes an occurrence, which by the nature of its severity, extent or timing might be regarded as an emergency (for example, contamination of water supply, structural damage to infrastructure or a danger to human health).

For any emergency, the ROL holder must:

- Notify the chief executive immediately; and
- Provide a report to the chief executive on the emergency including details of the emergency, conditions under which the emergency occurred, any responses or activities carried out as a result of the emergency and any impacts on the ROP.

# Attachment 4.3H

## Lower Fitzroy Water Supply Scheme

### Water allocation change rules

#### 1 Permitted changes

The permitted changes apply only to water allocations with purpose ‘agriculture’ or ‘any’

Application for the following changes to a water allocation will be approved. On approval, a change certificate will be issued by the chief executive, which may be lodged with the registrar of water allocations.

##### 1.1 Location

A change to the location of a water allocation from zone Fitzroy B to Fitzroy C, or from Fitzroy C to Fitzroy B.

For the permitted changes to the location of a water allocation given in this section, conversion factors do not apply to the volume for the water allocation – that is, the volume for the water allocation will be the same before and after the change of location. However, this does not preclude consideration of conversion factors to enable changes under Section 3.

##### 1.2 Priority

A change to the priority of a water allocation from medium to high or from high to medium, provided:

- The conversion rate is 1.5 ML of medium priority water converts to 1 ML of high priority water allocation;
- The maximum volume of high priority water allocation supplied through the scheme is 25,800 ML; and
- The minimum volume of high priority water allocation supplied through the scheme is 25,200 ML.

##### 1.3 Purpose

A change to the purpose of a water allocation from ‘any’ to ‘agriculture’ or from ‘agriculture’ to ‘any’.

##### 1.4 Amalgamation or subdivision

A change to subdivide a water allocation provided:

- The sum of the nominal volumes of the new water allocations is equal to the nominal volume of the water allocation that is being subdivided; and
- The location and priority group of the new water allocations is the same as that of the water allocation that is being subdivided.

A change to amalgamate water allocations provided:

- The nominal volume of the new water allocation is equal to the sum of the nominal volumes of the water allocations that are being amalgamated;
- The location and priority group of the water allocations that are being amalgamated are the same; and
- The location and priority group for the new water allocation is the same as that of the water allocations that are being amalgamated.

## **2 Prohibited changes**

The following changes are prohibited changes:

### **2.1 Location**

A change to a location that is not within the extent of the Dawson Valley, Nogoia Mackenzie, Lower Fitzroy or Fitzroy Barrage water supply schemes.

### **2.2 Priority group**

A change to a priority group that is not medium or high.

### **2.3 Purpose**

A change to a purpose that is not 'agriculture' or 'any'.

### **2.4 Volume**

A change to the volume that is not a consequence of a change to another attribute of a water allocation.

### **2.5 Other**

A change that requires an amendment to this ROP.

## **3 Application for change under Section 130 of the Water Act**

If a water allocation holder wishes to apply for a change to a water allocation that is not permitted under Section 1, and not prohibited under Section 2, an application may be made under Section 130 of the Water Act for the change.

The chief executive will deal with applications made under Section 130 of the Water Act, in accordance with the Water Act. That process is as follows:

- Notice of the application is published in local newspapers. The notice includes information about where the application can be inspected and invites submissions from the public on the application;
- The chief executive determines if the application should be approved having regard to the potential impact on a range of interests including other entitlement holders and aquatic ecosystems;
- If the chief executive approves the application, the chief executive will issue a change certificate that may be lodged with the registrar of water allocations; and
- If the chief executive refuses the application, the Water Act provides for an appeal process.

### **3.1 Purpose**

Any application to change the purpose of a water allocation from 'distribution loss' to 'any' must be supported by information to substantiate to the satisfaction of the chief executive an efficiency gain within the channel system. An application may be made for efficiency gains made since the issue of the interim resource operations licence for the Lower Fitzroy Water Supply Scheme in November 2000.

### **4 Registration of change**

If an application to change a water allocation is approved, the chief executive will issue a change certificate. The water allocation holder may lodge the change certificate with the registrar of water allocations who will change the water allocation on the water allocation register.

However, the registrar will not register the change until a supply contract has been entered into between the water allocation holder and the Resource Operations Licence holder for supply of the changed water allocation.

# Attachment 4.3I

## Lower Fitzroy Water Supply Scheme

### Amending critical water supply management arrangements

#### 1 Critical water supply management arrangements

##### 1.3 Introduction

The Resource Operations Plan (ROP) rules for infrastructure operation and environmental management (refer Attachment 4.3E) and for water sharing (refer Attachment 4.3F) include arrangements for dealing with periods of low water availability. These arrangements are referred to as the critical water supply management arrangements.

The critical water supply management arrangements initially specified in the ROP are based on broad-scale basin-wide hydrologic modelling. These initial arrangements may need to be refined and further developed to ensure the arrangements appropriately deal with local issues and circumstances particular to the Lower Fitzroy Water Supply Scheme.

Over time the arrangements can also be amended to allow adaptation to changing circumstances and refinement through improved knowledge about the operation of the system at times of low water supply.

For example, the critical water supply water sharing rules given in Attachment 4.3F deal with situations when supply to medium priority water allocations must cease to secure high priority water allocations. The initial arrangements for sharing the available supplies may warrant ongoing development to secure supplies for essential water needs.

Variations to the rules associated with the minimum operating levels for storages and to the waterhole drawdown limits given in Attachment 4.3E may also be considered to accommodate local water user and environmental needs under particular circumstances.

##### 1.2 Criteria for critical water supply management arrangements

Critical water supply management arrangements must have regard to the following:

- Provision of water for essential water needs must have first priority;
- The objectives of the Water Resource Plan;
- The effects on water operation security performance;
- The effects on natural ecosystems and the physical integrity of the watercourse; and
- The public interest.

For the purpose of the critical water supply management arrangements, essential water needs must include that part of a town water supply required for essential services including drinking water and sanitation but excluding lawns and gardens. The Resource Operations Licence (ROL) holder in conjunction with water allocation holders may establish additional essential purposes.

### **1.3 Initial review of the critical water supply management arrangements**

The ROL holder must undertake an initial review of the suitability of the critical water supply management arrangements. A report on the initial review must be provided to the chief executive within 12 months of the commencement of the ROP.

The initial review must include recommendations on whether amendments to the arrangements should be considered.

### **1.4 Proposals to amend the critical water supply management arrangements**

The ROL holder may submit a proposal to amend the critical water supply management arrangements at any time.

The chief executive may require the ROL holder to prepare a proposal to amend the critical water supply management arrangements at any time.

If the initial review of the critical water supply management arrangements under Section 1.3 indicates changes to the arrangements should be considered, the chief executive may require the ROL holder to prepare a proposal to amend the critical water supply management arrangements within a timeframe set by the chief executive.

A proposal to amend the critical water supply management arrangements must include:

- Proposed changes to the rules for infrastructure operation and environmental management (refer Attachment 4.3E) and for water sharing (refer Attachment 4.3F);
- An assessment of the effects of the proposal on natural ecosystems and the physical integrity of the watercourse and the proposed environmental monitoring requirements;
- Details of consultation with stakeholders including water users, local communities and environmental interests; and
- Any other information that will assist the chief executive to decide the proposal.

### **1.5 Amending the critical water supply management arrangements**

The chief executive may amend the rules for infrastructure operation and environmental management (refer Attachment 4.3E) and for water sharing (refer Attachment 4.3F) that apply during periods of low water availability. The chief executive will consider the following in deciding to amend the rules:

- Any proposal to amend the critical water supply management arrangements submitted by the ROL holder; and
- The criteria given in Section 1.2.

### **1.6 Evaluation of critical water supply management arrangements**

The ROL holder must annually evaluate the critical water supply management arrangements in regard to their suitability for periods of low water availability.

# Attachment 4.4B

## Fitzroy Barrage Water Supply Scheme

### Rules for conversion to water allocations

#### 1 Locations where existing authorisations are being converted to water allocations

Existing authorisations for supplemented water are being converted to water allocations on:

- The Fitzroy River from the upstream limit of the Fitzroy Barrage to the Fitzroy Barrage; and
- Sections of tributaries of the Fitzroy River that contain water ponded by the Fitzroy Barrage.

#### 2 Rules for conversion of existing authorisations to water allocations

The following rules apply for the conversion of existing authorisations to water allocations to establish the details required for the registration of supplemented water allocations.

##### 2.1 Location

The location from which water may be supplied under a water allocation is specified as a zone according to the position of the existing authorisation. Descriptions of the zones for the Fitzroy River are given in Attachment 2.3.

##### 2.2 Purpose

The purpose for which water may be taken under a water allocation is specified as either 'agriculture' or 'any'. 'Agriculture' is the nominated purpose for those existing authorisations that are primarily used for agricultural purposes. 'Any' is the nominated purpose for all other uses of water.

##### 2.3 Volume

The nominal volume for a water allocation will be the volume stated on existing authorisations subject to the following arrangements for entitlements associated with watering stock normally depastured on the land and domestic purposes.

Under the Water Act, an owner of land adjoining a watercourse, lake or spring may take water for domestic purposes and watering stock that would be normally depastured on the land without a water entitlement. Therefore any existing authorisation that provides for the taking of water for stock and domestic purposes on land adjoining a watercourse will not be converted to a water allocation.

**2.3.1 Arrangements for authorisations for irrigation and stock and domestic purposes**

- a) For an authorisation for irrigation, stock and domestic purposes, where all the land supplied adjoins a watercourse:
- If the authorisation states an irrigation volume and a stock and domestic volume, the irrigation volume is the volume for the water allocation; or
  - If the authorisation states an irrigation volume but not a stock and domestic volume, the irrigation volume is the volume for the water allocation.
- b) For an authorisation for irrigation, stock and domestic purposes, where all the land supplied does not adjoin a watercourse:
- If the authorisation states an irrigation volume and a stock and domestic volume, the combined irrigation volume and stock and domestic volume is the total volume for the water allocation; or
  - If the authorisation states an irrigation volume but not a stock and domestic volume, the irrigation volume is the volume for the water allocation.
- c) For an authorisation for irrigation, stock and domestic purposes, where part of the land supplied is not contiguous with the land that adjoins a watercourse:
- If the authorisation states an irrigation volume and a stock and domestic volume, the combined irrigation volume and the calculated volume for stock and domestic purposes on the non-adjointing land is the volume for the water allocation; or
  - If the authorisation states an irrigation volume but not a stock and domestic volume, the irrigation volume is the volume for the water allocation.
- d) For an authorisation for stock and domestic purposes only, where all the land supplied does not adjoin a watercourse:
- If the authorisation states a stock and domestic volume, the stock and domestic volume is the volume for the water allocation; or
  - If the authorisation does not state a stock and domestic volume, the annual volume calculated for stock and domestic purposes is the volume for the water allocation.
- e) For Section 2.3.1c) and Section 2.3.1d), the annual volume calculated for domestic purposes is:
- i) 1 ML; or
  - ii) An alternative volume determined by the chief executive based on consideration of a submission received on this matter on the draft Resource Operations Plan (ROP).
- f) For Section 2.3.1c) and Section 2.3.1d) the annual volume calculated for stock watering is:
- i) A volume equivalent to 1 ML per 250 ha of land; or
  - ii) An alternative volume determined by the chief executive based on consideration of a submission received on this matter on the draft ROP.

Where an existing authorisation does not state a stock and domestic volume, the annual volume specified for the water allocation is the combined volume calculated using Section 2.3.1e)i) and Section 2.3.1f)i).

## **2.4 Priority group**

The priority group for a water allocation converted from an existing authorisation to take supplemented water is medium priority, except where a product specification or other undertaking associated with the authorisation identifies the authorisation's water supply as being high priority water allocation.

# Attachment 4.4C

## Fitzroy Barrage Water Supply Scheme

### Total volume of supplemented water allocations

**Table 1: Total volume of supplemented water allocations at Resource Operations Plan approval**

<b>Zone</b>	<b>Medium priority water allocation (ML)</b>	<b>High priority water allocation (ML)</b>
<b>Fitzroy A</b>	12,335 (note 1)	50,000

*Note 1: Includes 575 ML granted to Rockhampton City Council under Section 6.2.6 of Chapter 6.*

# Attachment 4.4D

## Fitzroy Barrage Water Supply Scheme Infrastructure details

### Storage: Fitzroy Barrage – Fitzroy River AMTD 59.6 km

<b>Description of water infrastructure</b>	
Main embankment	Concrete embankment with vertical lift gates
Full supply level	EL 3.78 m AHD (plus or minus 0.05 metres)
Fixed crest level	EL 0.61 m AHD
Saddle dam(s)	Nil
Fabridams	Nil
Gates	Eighteen vertical lift gates, each 12.2 metres wide and 3.3 metres high
<b>Storage volume and surface area</b>	
Full supply volume	81,300 ML (at EL 3.78 m AHD)
Dead storage volume	21,900 ML (at EL -1.2 m AHD)
Storage volume/surface area/elevation relationship	Natural Resources Drawing No. A3-209321 (March 1998)
<b>Spillway arrangement</b>	
Description of works	<ul style="list-style-type: none"> <li>• 18 gated weir monoliths, 14 metres in length with 12.2 metre wide bays for vertical lift gates, with a concrete crest at EL 0.61 m AHD</li> <li>• Four 12.2 metre wide bays with a concrete crest at EL 3.91 m AHD</li> </ul>
Spillway level	EL 0.61 m AHD
Spillway width	As described above
Discharge characteristics	Not available
<b>River inlet/outlet works</b>	
Description of works	18 gated weir monoliths, 14 metres in length with 12.2 metre wide bays for vertical lift gates, with a concrete crest at EL 0.61 m AHD
Multi-level inlet	Works do not accommodate selective withdrawal
Cease to flow level	EL 0.61 m AHD
Discharge characteristics	Not available
<b>Fish transfer system</b>	
Description of works	Vertical slot fish ladder, located on the right bank. Discharge capacity is approximately 18 ML/day at full supply level. Fish ladder operates above EL 3.2 m AHD and is permanently open.

# Attachment 4.4E

## Fitzroy Barrage Water Supply Scheme

### Rules for infrastructure operation and environmental management

#### 1 Operating level of storages and waterholes

##### 1.1 Nominal operating levels of Fitzroy Barrage

The nominal operating level for the Fitzroy Barrage is EL 3.38 m AHD (75,000 ML).

##### 1.2 Minimum operating level of Fitzroy Barrage

The minimum operating level for the Fitzroy Barrage is EL 1.2 m AHD (21,900 ML).

Water must not be supplied from the Fitzroy Barrage if the water level in the Barrage is below its minimum operating level, unless otherwise authorised by the chief executive.

#### 2 Releases of water from storages

##### 2.1 General rules

When determining releases to make from the Fitzroy Barrage, the Resource Operations Licence (ROL) holder must have regard to the following:

- When the Barrage is above its full supply level, releases from the Barrage should mimic, to the maximum extent possible, any inflows;
- The seasonal base flow management strategy; and
- The fishway management strategy.

##### 2.2 Release rate rules

No limits are specified for release rates.

#### 3 First post-winter flow management rules

##### 3.1 Fitzroy Barrage first post-winter flow management strategy

There is no first post-winter flow management strategy.

#### 4 Seasonal base flow management rules

A seasonal base flow equal to the inflow to Eden Bann Weir must pass Fitzroy Barrage if:

- Inflows to Eden Bann Weir are between 220 ML/day and 350 ML/day; and
- The water level in the Barrage is above EL 2.3 m AHD (59,400 ML).

A seasonal base flow of 350 ML/day must pass the Fitzroy Barrage if:

- Inflows to Eden Bann Weir are greater than 350 ML/day; and
- The water level in the Barrage is above EL 2.3 m AHD (59,400 ML).

For the purpose of implementing this strategy:

- The volume passed over a 48-hour period must be within plus 20% and minus 20% of the volume required to be passed under the strategy; and
- The commencement and cessation of any release required under this strategy may be delayed by up to 48 hours.

#### **5 Fishway management strategy**

The ROL holder is authorised to operate the Fitzroy Barrage fishway when the level of the water stored in the Barrage is above EL 3.2 m AHD.

#### **6 Quality of water released from the Fitzroy Barrage**

There are no specific rules specified by this ROP.

#### **7 Use of watercourses for distribution of water**

The ROL holder may use the following watercourses for the purposes of distribution of water:

- The Fitzroy River from the upstream limit of the Fitzroy Barrage to the Fitzroy Barrage; and
- Sections of tributaries of the Fitzroy River that contain water from natural waterholes and infrastructure within the above section of the Fitzroy River.

The ROL holder must not divert water to any watercourse other than those given above for distribution of water.

#### **8 Riparian stock and domestic use**

Under Section 20(3) of the Water Act, an owner of land adjoining a watercourse, lake or spring may take water for domestic purposes and watering stock that would be normally depastured on the land without a water entitlement. In this section this is referred to as 'riparian entitlement water'.

This means that riparian entitlement water might also be taken through the same metered water facilities as supplemented water and some users might desire appropriate allowances be made for their riparian entitlement water use. The historical arrangements for accounting for individual riparian use taken through metered facilities will not apply following commencement of the ROP.

**8.1 Rules for adjusting metered use for riparian entitlement water use**

This section provides arrangements to allow adjustments for riparian entitlement water metered use.

The ROL holder must enter into an arrangement with any water user who requests metered use adjustments for riparian entitlement water use taken through a metered facility. The ROL holder must supply details of the arrangement with each individual user to the chief executive within 5 business days of an agreement.

An arrangement must comply with departmental guidelines for this purpose.

If the ROL holder and a water user are unable to reach agreement on an arrangement, the chief executive will decide the arrangement that will apply in that particular instance.

# Attachment 4.4F

## Fitzroy Barrage Water Supply Scheme

### Water sharing rules

This attachment provides water sharing rules for:

- Announced allocations;
- Critical water supply;
- Transfer of water between water years; and
- Seasonal water assignments.

#### **1 Announced allocation**

##### **1.1 General rules**

The water year for the Fitzroy Barrage Water Supply Scheme is from 1 July to 30 June in the following year.

##### **1.2 Calculation of announced allocation percentages**

###### **1.2.1 Medium priority water allocations**

The announced allocation percentage for medium priority water allocations must be 100%.

###### **1.2.2 High priority water allocations**

The announced allocation percentage for high priority water allocations must be 100%.

#### **2 Critical water supply water sharing rules**

##### **2.1 Critical water supply water sharing rules during the medium priority restriction period**

For the Lower Fitzroy and the Fitzroy Barrage water supply schemes, the announced allocation must be 100% for both medium and high priority water. This means that at times the total medium priority allocation cannot be supplied without increasing the risk to high priority supply security.

This risk during critical water supply periods is addressed by preventing the supply of medium priority entitlements when the Fitzroy Barrage is below specified levels. In addition, the maximum allowable distribution of supply of high priority entitlement will be constrained during those periods when medium priority supply is restricted.

### 2.1.1 Medium priority restriction rule

Medium priority water allocation supply through the Fitzroy Barrage Water Supply Scheme must:

- Cease when the water level in the Fitzroy Barrage falls below EL 0.75 m AHD (40,500 ML); and
- Not recommence unless the water level in the Fitzroy Barrage has risen above EL 0.85 m AHD (41,600 ML).

A period when the water level in the Fitzroy Barrage has fallen below EL 0.75 m AHD and not re-risen to above EL 0.85 m AHD is a ‘medium priority restriction period’.

### 2.1.2 High priority water use during the medium priority restriction period

During a medium priority restriction period referred to in Section 2.1.1, the holder of a high priority water entitlement must not be supplied more than a specified maximum volume during a specified period as defined by the high priority demand pattern assigned to the entitlement. The high priority demand pattern for water allocations is referred to in Section 2.1.3.

An entitlement may also include a seasonal water assignment of a high priority allocation referred to in Section 4.

### 2.1.3 High priority demand pattern

The Resource Operations Licence (ROL) holder must assign to each high priority water allocation a ‘high priority demand pattern’.

The high priority demand pattern has effect only when a medium priority restriction period is in effect.

During a medium priority restriction period, the high priority demand pattern defines the maximum amount of water that may be supplied under a high priority water allocation for specified calendar periods (for example, on a specific date, or a specific week, or a specific month). Any specified period must not be greater than 1 month.

The combined total of the high priority demand patterns for high priority water allocations supplied by the Fitzroy Barrage Water Supply Scheme must not exceed the limits in Table 1.

**Table 1: Maximum percentage of total high priority water allocation in Fitzroy Barrage Water Supply Scheme that may be assigned to the specified period under the high priority demand pattern**

Period	Percentage of total high priority allocation
July to September	31
October to December	34
January to March	34
April to June	31

#### **2.1.4 Other restrictions**

During the medium priority restriction period, the ROL holder may implement further restrictions on the supply of high priority water, decided by the ROL holder in conjunction with high priority water allocation holders for the purpose of extending the period that water supplies are available, provided the objectives of the Water Resource Plan (WRP) are not compromised.

### **3 Transfer of water between water years**

The ROL holder may develop and apply scheme practices for forward draw of water entitlements in accordance with the principles and rules in this section.

#### **3.1 Principles for transfer of water between water years**

The ROL holder must have regard to the following principles in developing and applying scheme practices for forward draw of water entitlements

Forward draw practices must not have an adverse impact on the objectives of the WRP.

Entitlements must not be:

- Carried over from the current water year to any future year, other than a minor carry over adjustment under Section 3.3; or
- Brought forward from a future water year to the current water year, other than from the next water year.

The volume of individual water allocation brought forward to the current water year must not exceed the announced allocation volume for the allocation at the start of the next water year.

#### **3.2 Rules for transfer of water between water years**

The following rule applies for the transfer of water between water years.

The total volume permitted to be brought forward to a water year must not exceed 2% of the total nominal volume.

#### **3.3 End of water year minor adjustments**

As an administrative arrangement to account for the timing of the end of water year metered use reading and for the operational convenience of water users, the ROL holder may, in addition to any forward draw permitted under Section 3.1 and Section 3.2, make minor carry over and forward draw adjustments to entitlements. For an individual, the adjustments must not exceed 2% of the individual entitlement at the end of the water year for which the meter reading applies, or 10 ML whichever is the lesser.

### **4 Seasonal water assignment rules**

Under Section 146B of the Water Act, the holder of a water allocation may enter into an arrangement for a seasonal assignment in relation to the allocation. However the allocation holder may enter into the arrangement only with the consent of the ROL holder. The ROL holder may give consent only if the assignment is allowed under the seasonal water assignment rules in the ROP.

High priority water supply during medium priority restriction periods (Refer to Section 2) must comply with specified high priority demand patterns. A seasonal water assignment of a high priority water allocation also requires an assigned demand pattern for the purposes of Section 2.

The ROL holder is required to report (refer Section 4.1.1 Attachment 4.4G) on trends in seasonal assignment and evaluate whether seasonal assignment practices are impacting on supply for individual water users or groups of water users or impacting on the objectives of the WRP.

Chapter 8 of the ROP allows the chief executive to initiate changes to the seasonal assignment rules if considered necessary to protect the objectives of the WRP.

#### **4.1 Principles for seasonal water assignment**

The ROL holder must have regard to the following principles in developing scheme practices and for making decisions for consent of seasonal water assignment arrangements.

The effects of an individual seasonal assignment and the cumulative effects of successive or repeated seasonal assignments must not:

- Impact adversely on the WRP objectives;
- Impact adversely on the availability of water to other water users in any part of the scheme; or
- Subject waterholes to an increased potential for environmental harm.

Water with a location zone Fitzroy A must continue to be supplied in zone Fitzroy A.

#### **4.2 Rules for seasonal water assignment**

The following rules apply in developing scheme practices and for making decisions for consent of seasonal water assignment arrangements.

Water supplied under a seasonal water assignment may be used for any purpose.

A high priority demand pattern must be assigned to a seasonal water assignment of a high priority water allocation, the 'original entitlement', for the purposes of Section 2. An adjusted high priority demand pattern must be assigned for the 'original allocation' to account for the seasonal assignment. The combined demand patterns for the resultant entitlements must not exceed the demand pattern for the original entitlement.

# Attachment 4.4G

## Fitzroy Barrage Water Supply Scheme Monitoring program

### 1 Water quantity

#### 1.1 Height and stream flow

The Resource Operations Licence (ROL) holder must record height and flow data in accordance with Table 1.

**Table 1: Locations in the Fitzroy River where height and flow data is required**

Location	Height data	Flow data
Fitzroy Barrage inflow*		✓
Fitzroy Barrage storage	✓	
Fitzroy Barrage outflow		✓
Eden Bann Weir inflow		✓

*\*The inflow to the Fitzroy Barrage is taken to be the flow in the Fitzroy River anywhere from the Fitzroy Barrage storage limit upstream to Wattlebank.*

It is preferred that continuous time series data be collected. However, the chief executive may approve the collection of data in a format and standard other than for continuous time series data.

The methodology for determining height and flow data, including data format and standard, must be approved by the chief executive.

#### 1.1a Operating level of storages

The ROL holder must record under Section 1 of Attachment 4.4E:

- The daily storage height for the Fitzroy Barrage.

For the purposes of this section:

- The methodology for determining the daily storage height must be approved by the chief executive; and
- The data must be real time information upon which operational decisions were based not data that has subsequently changed for example through a verification process.

#### 1.1b Stream flow for the purpose of seasonal base flow management strategies

The ROL holder must record under Section 4 of Attachment 4.4E:

- The daily storage inflow volume for Eden Bann Weir;
- The daily storage height for the Fitzroy Barrage; and
- The daily storage outflow for the Fitzroy Barrage.

For the purposes of this section:

- The methodology for determining the daily storage inflow volume, daily storage height

and daily storage outflow must be approved by the chief executive; and

- The data must be real time information upon which operational decisions for the implementation of the strategy were based not data that has subsequently changed for example through a verification process.

### **1.2 Releases from storages**

The ROL holder must record details of the basis for each release decision for the Fitzroy Barrage under the rules for releases of water from storages given in Section 2 of Attachment 4.4E, including:

- The general rules for releases; and
- The seasonal base flow and fishway management strategies.

The ROL holder must record the daily volume released from the Fitzroy Barrage.

### **1.3 Announced allocations**

The ROL holder must record details of announced allocation determinations referred to in Section 1 of Attachment 4.4F.

### **1.4 Restrictions on the taking of medium priority water during the medium priority restriction period**

The ROL holder must record details of any restrictions on the taking of medium priority water referred to in Section 2.1.1 of Attachment 4.4F, including:

- The date of the restriction;
- The nature of the restriction; and
- The basis for the determination of the restriction.

### **1.5 Restrictions on the taking of high priority water during medium priority restriction period**

The ROL holder must record details of any restrictions on the taking of high priority water referred to in Section 2.1.2 and Section 2.1.3 of Attachment 4.4F, including:

- The date of the restriction;
- The nature of the restriction; and
- The basis for the determination of the restriction.

### **1.6 Transfer of water between water years**

The ROL holder must record details of the movement of water between water years referred to in Section 3 of Attachment 4.4F, including:

- The basis of each decision to adjust the amount of water an individual may be supplied in a water year and the volume of the adjustment;
- The basis of each decision to approve a forward draw for each individual water user; and
- The volume of water brought forward from the next water year to a water year by priority group.

### **1.7 Seasonal water assignment**

The ROL holder must record details of individual seasonal water assignment arrangements,

including assigned high priority demand patterns.

### **1.8 Water taken by water users**

The ROL holder must record the volume of water taken by water users as follows:

- For each individual water user specified for each zone:
  - The total volume of supplemented water taken each quarter;
  - The total volume of supplemented water entitled to be taken at any time;
  - The basis for determining the total volume of supplemented water entitled to be taken at any time, including any adjustments for approved seasonal water assignments and transfers into or out of the water years;
  - The total volume of metered water taken as ‘riparian entitlement water’; and
  - The zone.

### **1.9 High priority demand pattern**

The ROL holder must record details of individual high priority demand patterns, referred to in Section 2.1.3 of Attachment 4.4F.

## **2 Impact of storage operation on aquatic ecosystems**

The ROL holder must undertake the following to establish any impacts on aquatic ecosystems that are potentially related to the operation of storages.

### **Section 2.1 Bank condition**

The ROL holder must inspect banks for evidence of collapse and/or erosion within the ponded area of the Fitzroy Barrage following instances of rapid water level changes or large flows through the Fitzroy Barrage, or other occasions when collapse and/or erosion of banks may be likely.

Any instances of bank slumping or erosion observed must be investigated to determine if the instability was associated with the nature or operation of the infrastructure.

### **2.2 Water Quality**

The ROL holder must monitor water quality in relation to relevant infrastructure in accordance with the department’s Water Monitoring Data Collection Standard.

### **2.3 This section not required**

## **3 Reporting**

There are four levels of reporting for ROL holders:

- Quarterly report for the previous quarter;
- Annual report for the previous water year;
- Operational reports; and
- Emergency reports.

### **3.1 Quarterly report**

The ROL holder must transfer the following data to the chief executive:

- Water quantity all records referred to in Sections 1.1a and 1.1b;
- A summary of bank condition monitoring and incidences of slumping referred to in Section 2.1;
- Water quality all records referred to in Section 2.2; and
- Seasonal water assignments all records referred to in section 1.7.

### **3.2 Annual report**

The annual report must include, but not be limited to, discussion and recommendations with regard to the monitoring results for the previous water year.

#### **3.2.1 Water monitoring**

A summary of the implementation of the rules for releases from storages, other than for seasonal base flow and fishway management.

A summary of the implementation of the seasonal base flow management strategy for the Fitzroy Barrage, including:

- Overview of strategy implementation, including the basis of decisions; and
- An evaluation of the seasonal base flow management arrangements and outcomes.

A summary of the implementation of the fishway management strategy for the Fitzroy Barrage, including:

- Overview of strategy implementation;
- Periods of operation of the fishway; and
- Total period of operation of the fishway.

A summary of announced allocation determinations, including:

- An evaluation of the announced allocation procedures and outcomes.

A summary of restrictions on the taking of medium priority water, including:

- An evaluation of the restriction procedures and outcomes; and
- The date and nature of each restriction decision.

A summary of restrictions on the taking of high priority water, including:

- An evaluation of the restriction procedures and outcomes; and
- The date and nature of each restriction decision.

A summary of the transfer of water between water years, including:

- An evaluation of the rules and outcomes;
- The total volume of water brought forward by priority group to the water year from the next water year; and
- The total volume of water brought forward by priority group from the water year to the previous water year.

A summary of the volume of water taken by water users, specified by zone, including:

- The total volume of supplemented water taken;
- The total volume of supplemented water entitled to be taken;

- The basis for determining the total volume of supplemented water entitled to be taken, including any adjustments for approved seasonal water assignments and transfers into or out of the water years;
- The announced allocation volume at the end of the water year;
- The total volume of supplemented water taken during a medium priority restriction period; and
- The total volume of metered water taken as ‘riparian entitlement water’.

A summary of seasonal water assignment arrangements, including:

- An evaluation of the seasonal water assignment rules and outcomes, including:
  - An evaluation of any circumstances of supply difficulties when the supply difficulties were linked to seasonal assignment practices; and
  - Identification of and reporting on any trends in seasonal water assignment;
- The total number of seasonal water assignment arrangements; and
- The total volume of water seasonally assigned.

Details of changes to Fitzroy Barrage or its operation that may have an impact on the implementation of the ROP.

Details of new monitoring devices such as equipment to measure stream flow.

### **3.2.2 Impact of storage operation on aquatic ecosystems**

#### **Bank condition**

A summary of bank condition monitoring including:

- Results of investigations of bank slumping or erosion identified in the ponded area of the Fitzroy Barrage; and
- Changes to operation of storages to reduce instances of bank slumping or erosion.

#### **Water quality**

Discussion and assessment of the following water quality issues:

- Thermal and chemical stratification in the Fitzroy Barrage;
- Water quality in the Fitzroy Barrage;
- Contribution of the storage and its management to the quality of water released; and
- Cyanobacteria population changes in response to stratification in the Fitzroy Barrage.

### **3.3 Operational reports**

The ROL holder must notify the chief executive within 1 business day of becoming aware of the following operational incidents:

- Noncompliance by the ROL holder with the rules given in the ROP;
- A decision relating to any restrictions on the taking of medium priority water; and
- A decision relating to any restrictions on the taking of high priority water.

The ROL holder must provide an operational report to the chief executive for an incident relating to noncompliance with the rules in the ROP, including details of the incident, conditions under which the incident occurred and any responses or activities carried out as a

result of the incident.

The ROL holder must provide a report to the chief executive within 5 business days of the start of the water year detailing the high priority demand patterns assigned to each high priority water allocation referred to in Section 2.1.3 of Attachment 4.4F. The report should include:

- Water allocation number;
- Holder of water allocation; and
- High priority demand pattern.

The ROL holder must provide a report to the chief executive within 5 business days of a change to the high priority demand pattern associated with a high priority water allocation, or the establishment of a new high priority water allocation. The report should include:

- Water allocation number;
- Holder of water allocation; and
- High priority demand pattern.

### **3.4 Emergency report**

An emergency for the purpose of this ROP includes an occurrence, which by the nature of its severity, extent or timing might be regarded as an emergency (for example, contamination of water supply, structural damage to infrastructure or a danger to human health).

For any emergency, the ROL holder must:

- Notify the chief executive immediately; and
- Provide a report to the chief executive on the emergency including details of the emergency, conditions under which the emergency occurred, any responses or activities carried out as a result of the emergency and any impacts on the ROP.

# Attachment 4.4H

## Fitzroy Barrage Water Supply Scheme

### Water allocation change rules

#### 1 Permitted changes

Application for the following changes to a water allocation will be approved. On approval, a change certificate will be issued by the chief executive, which may be lodged with the registrar of water allocations.

##### 1.1 Purpose

A change to the purpose of a water allocation from 'any' to 'agriculture' or from 'agriculture' to 'any'.

##### 1.2 Priority

A change to the priority of a water allocation from medium to high or from high to medium, provided:

- The conversion rate is 1.5 ML of medium priority water converts to 1 ML of high priority water allocation;
- The maximum volume of high priority water allocation supplied through the scheme is 51,200 ML; and
- The minimum volume of high priority water allocation supplied through the scheme is 48,800 ML.

##### 1.3 Amalgamation or subdivision

A change to subdivide a water allocation provided:

- The sum of the nominal volumes of the new water allocations is equal to the nominal volume of the water allocation that is being subdivided; and
- The location and priority group of the new water allocations is the same as that of the water allocation that is being subdivided.

A change to amalgamate water allocations provided:

- The nominal volume of the new water allocation is equal to the sum of the nominal volumes of the water allocations that are being amalgamated;
- The location and priority group of the water allocations that are being amalgamated are the same; and
- The location and priority group for the new water allocation is the same as that of the water allocations that are being amalgamated.

#### 2 Prohibited changes

The following changes are prohibited changes:

## **2.1 Location**

A change to a location that is not within the extent of the Dawson Valley, Nogoia Mackenzie, Lower Fitzroy or Fitzroy Barrage water supply schemes.

## **2.2 Priority group**

A change to a priority group that is not medium or high.

## **2.3 Purpose**

A change to a purpose that is not 'agriculture' or 'any'.

## **2.4 Volume**

A change to the volume that is not a consequence of a change to another attribute of a water allocation.

## **2.5 Other**

A change that requires an amendment to this ROP.

## **3 Application for change under Section 130 of the Water Act**

If a water allocation holder wishes to apply for a change to a water allocation that is not permitted under Section 1, and not prohibited under Section 2, an application may be made under Section 130 of the Water Act for the change.

The chief executive will deal with applications made under Section 130 of the Water Act, in accordance with the Water Act. That process is as follows:

- Notice of the application is published in local newspapers. The notice includes information about where the application can be inspected and invites submissions from the public on the application;
- The chief executive determines if the application should be approved having regard to the potential impact on a range of interests including other entitlement holders and aquatic ecosystems;
- If the chief executive approves the application, the chief executive will issue a change certificate that may be lodged with the registrar of water allocations; and
- If the chief executive refuses the application, the Water Act provides for an appeal process.

## **4 Registration of change**

If an application to change a water allocation is approved, the chief executive will issue a change certificate. The water allocation holder may lodge the change certificate with the registrar of water allocations who will change the water allocation on the water allocation register.

However, the registrar will not register the change until a supply contract has been entered into between the water allocation holder and the Resource Operations Licence (ROL) holder for supply of the changed water allocation.

# Attachment 4.4I

## Fitzroy Barrage Water Supply Scheme

### Amending critical water supply management arrangements

#### 1 Critical water supply management arrangements

##### 1.4 Introduction

The Resource Operations Plan (ROP) rules for infrastructure operation and environmental management (refer Attachment 4.4E) and for water sharing (refer Attachment 4.4F) include arrangements for dealing with periods of low water availability. These arrangements are referred to as the critical water supply management arrangements.

The critical water supply management arrangements initially specified in the ROP are based on broad-scale basin-wide hydrologic modelling. These initial arrangements may need to be refined and further developed to ensure the arrangements appropriately deal with local issues and circumstances particular to the Fitzroy Barrage Water Supply Scheme.

Over time the arrangements can also be amended to allow adaptation to changing circumstances and refinement through improved knowledge about the operation of the system at times of low water supply.

For example, the critical water supply water sharing rules given in Attachment 4.4F deal with situations when supply to medium priority water allocations must cease to secure high priority water allocations. The initial arrangements for sharing the available supplies may warrant ongoing development to secure supplies for essential water needs.

Variations to the rules associated with the minimum operating levels for storages and to the waterhole drawdown limits given in Attachment 4.4E may also be considered to accommodate local water user and environmental needs under particular circumstances.

##### 1.2 Criteria for critical water supply management arrangements

Critical water supply management arrangements must have regard to the following:

- Provision of water for essential water needs must have first priority;
- The objectives of the Water Resource Plan;
- The effects on water allocation security performance;
- The effects on natural ecosystems and the physical integrity of the watercourse; and
- The public interest.

For the purpose of the critical water supply management arrangements, essential water needs must include that part of a town water supply required for essential services including drinking water and sanitation but excluding lawns and gardens. The Resource Operations Licence (ROL) holder in conjunction with water allocation holders may establish additional essential purposes.

### **1.3 Initial review of the critical water supply management arrangements**

The ROL holder must undertake an initial review of the suitability of the critical water supply management arrangements. A report on the initial review must be provided to the chief executive within 12 months of the commencement of the ROP.

The initial review must include recommendations on whether amendments to the arrangements should be considered.

### **1.4 Proposals to amend the critical water supply management arrangements**

The ROL holder may submit a proposal to amend the critical water supply management arrangements at any time.

The chief executive may require the ROL holder to prepare a proposal to amend the critical water supply management arrangements at any time.

If the initial review of the critical water supply management arrangements under Section 1.3 indicates changes to the arrangements should be considered, the chief executive may require the ROL holder to prepare a proposal to amend the critical water supply management arrangements within a timeframe set by the chief executive.

A proposal to amend the critical water supply management arrangements must include:

- Proposed changes to the rules for infrastructure operation and environmental management (refer Attachment 4.4E) and for water sharing (refer Attachment 4.4F);
- An assessment of the effects of the proposal on natural ecosystems and the physical integrity of the watercourse and the proposed environmental monitoring requirements;
- Details of consultation with stakeholders including water users, local communities and environmental interests; and
- Any other information that will assist the chief executive to decide the proposal.

### **1.5 Amending the critical water supply management arrangements**

The chief executive may amend the rules for infrastructure operation and environmental management (refer Attachment 4.4E) and for water sharing (refer Attachment 4.4F) that apply during periods of low water availability. The chief executive will consider the following in deciding to amend the rules:

- Any proposal to amend the critical water supply management arrangements submitted by the ROL holder; and
- The criteria given in Section 1.2.

### **1.6 Evaluation of critical water supply management arrangements**

The ROL holder must annually evaluate the critical water supply management arrangements in regard to their suitability for periods of low water availability.

# Attachment 5.1A

## Dawson Valley Water Management Area

### Amending waterharvesting authorisations

---

#### 1 Locations where waterharvesting authorisations will be amended

Waterharvesting licences will be amended on the Dawson River from the upstream limit of Glebe Weir to the Fitzroy River junction.

#### 2 Details for amendment of waterharvesting licences

Amendments will be made to waterharvesting water licences as follows:

##### 2.1 Location

The location from which water may be taken under a water licence will be amended to include a zone according to the position of the existing authorisation. Descriptions of the zones for the Dawson River are given in Attachment 2.1.

##### 2.2 Operating rules

The terms and conditions about the arrangements for the taking of water stated on existing licences will be replaced by reference to the operating rules given in Attachment 5.1B.

# Attachment 5.1B

## Dawson Valley Water Management Area

### Operating rules for water licences for waterharvesting with 15 and 30 cumec flow conditions

These operating rules apply to water licences for waterharvesting with 15 and 30 cumec flow conditions in the Dawson Valley Water Management Area, from the upstream limit of Glebe Weir to the Fitzroy River junction.

#### **1 Water year**

The water year is from 1 October to 30 September the following year.

#### **2 Flow conditions under which water may be taken**

The flow conditions stated on water licences for waterharvesting is the stream flow nominally required to pass downstream while water is being taken.

The chief executive will determine when the flow conditions exist and when water may be taken under arrangements given in Sections 3 and 4. A period of time during which water may be taken is referred to as an announced period.

#### **3 Announced periods for taking water**

The chief executive will notify water licence holders of the start and of the end of an announced period during which water may be taken.

Water may only be taken during announced periods, unless the chief executive has authorised an individual water licence holder to take water outside of an announced period.

In some circumstances a water licence holder may experience difficulty taking water during all or part of an announced period because of the characteristics of the flow event and the flow management location where the passing flow conditions are assessed under Section 4. Under these circumstances the chief executive may authorise a water licence holder to take water outside an announced period under alternative arrangements if the chief executive is satisfied that:

- No significant adverse impacts on other water users are expected; and
- The authorisation given does not exceed the announced period applying to other water licences in the same locality.

#### 4 Determining announced periods for taking water

Subject to the requirements of the first post-winter flow management strategies in Section 5, for each management reach in Table 1 the chief executive will estimate the start and the end of a period during which the stream flow is estimated to exceed the flow conditions for each water licence group. The stream flow will be assessed at the flow management locations in Table 1.

The announced period is subject to the following conditions:

- The chief executive may delay the notification of the start of an announced period up to a maximum of 24 hours from the estimated time when the passing flow conditions exist, provided the notification of the end of the announced period is extended by a similar time;
- The typical duration of an announced period should not vary by more than 12 hours from the total estimated time that the passing flows exist. The chief executive may extend a subsequent announced period to adjust for any variations in excess of 12 hours; and
- The chief executive may use information about stream flow other than at the flow management locations in Table 1 to determine an announced period.

**Table 1: Management reaches and flow management locations for water licences with 15 and 30 cumec flow conditions**

Management reach	Management reach description	Flow management location
<b>Zones: Dawson A, B.</b>	Don River junction to Fitzroy River junction	Don River junction
<b>Zones: Dawson C, D, E.</b>	Mimosa Creek junction to Don River junction	Neville Hewitt Weir tailwater
<b>Zones: Dawson F, G.</b>	Effective upstream limit of Moura Weir to Mimosa Creek junction	Moura Weir tailwater
<b>Zones: Dawson H, I.</b>	Effective upstream limit of Theodore Weir to effective upstream limit of Moura Weir	Theodore Weir tailwater
<b>Zones: Dawson J.</b>	Orange Ck Weir to effective upstream limit of Theodore Weir	Isla Delusion Crossing
<b>Zones: Dawson K.</b>	Effective upstream limit of Gylanda Weir to Orange Ck Weir	Gylanda Weir tailwater
<b>Zones: Dawson L, M.</b>	Upstream limit of Glebe Weir to effective upstream limit of Gylanda Weir	Glebe Weir tailwater

## **5 Environmental flow management rules**

### **5.1 First post-winter flow management strategy for waterharvesting upstream of the Mimosa Creek junction (Zones: Dawson F to Dawson M)**

The following first post-winter flow management strategy applies to waterharvesting upstream of the Mimosa Creek junction.

The first post-winter flow management strategy commences at the earlier of:

- Activation of the upper Dawson sub-scheme first post-winter flow management strategy for the Dawson Valley Water Supply Scheme; or
- 1 October.

The first post-winter flow management strategy ends at the earlier of:

- 6 days of flow greater than 15 cumec passing any of the flow management locations in Table 1 that are located upstream of the Mimosa Creek junction since the commencement of the strategy; or
- Finalisation of the upper Dawson sub-scheme first post-winter flow management strategy for the Dawson Valley Water Supply Scheme; or
- 30 April.

For the full duration of the first post-winter flow management strategy, the chief executive will apply a 30 cumec flow condition for all announced periods for waterharvesting.

### **5.2 First post-winter flow management strategy for waterharvesting downstream of the Mimosa Creek junction (Zones: Dawson A to Dawson E)**

The following first post-winter flow management strategy applies to waterharvesting downstream of the Mimosa Creek junction.

The first post-winter flow management strategy commences at the earlier of:

- Activation of the lower Dawson sub-scheme first post-winter flow management strategy for the Dawson Valley Water Supply Scheme; or
- 1 October.

The first post-winter flow management strategy ends at the earlier of:

- 6 days of flow greater than 15 cumec passing any of the flow management locations in Table 1 that are located downstream of the Mimosa Creek junction since the commencement of the strategy; or
- Finalisation of the lower Dawson sub-scheme first post-winter flow management strategy for the Dawson Valley Water Supply Scheme; or
- 30 April.

For the full duration of the first post-winter flow management strategy, the chief executive will apply a 30 cumec flow condition for all announced periods for waterharvesting.

## **6 Assessment of quantity of unsupplemented water taken**

For the assessment of the quantity of unsupplemented water taken under a water licence:

- A water licence holder must advise the chief executive prior to taking unsupplemented water;
- A water licence holder must provide recordings of water taken to the chief executive;
- Only water taken during announced periods may be taken as unsupplemented water unless otherwise authorised by the chief executive under Section 3;
- The chief executive will advise the Resource Operations Licence holder for the Dawson Valley Water Supply Scheme of the meter readings and the approved quantities of unsupplemented water taken within 7 business days of the conclusion of announced periods for all management reaches in the Dawson Valley Water Management Area; and
- Any water taken that is not in accordance with these rules for unsupplemented water and taken from within the limits of the Dawson Valley Water Supply Scheme will be treated as supplemented water.

## **7 Seasonal water assignment rules**

The assignment of the benefit of a water licence to another person for a water year for all or part of the water that may be taken under the water licence is referred to as a seasonal water assignment.

Seasonal water assignment of water licences in the Dawson Valley Water Management Area is not permitted.

## **8 Procedures**

Details of procedures associated with the implementation of these operating rules may be obtained from the chief executive.

# Attachment 5.2A

## Nogoa Mackenzie Water Management Area

### Details of conversions to water allocations

Water allocation number	Family name/ Company	Given names	Tenancy type	Tenancy comments	Share of water allocation	Location (AMTD km)	Purpose	Nominal volume (ML/water year)	Volumetric limit (ML/ water year)	Maximum rate (L/s)	Flow conditions	Water allocation group	Converting authorisation
203	[REDACTED]	[REDACTED]	SP		1	Mackenzie A (311.2)	Agriculture	211	240	40	No flow conditions apply	Class 4C	15650U

# **Attachment 5.2B**

## **Nogoa Mackenzie Water Management Area**

### **Rules for conversion of existing waterharvesting authorisations to water allocations**

---

#### **1 Locations where existing waterharvesting authorisations are being converted to water allocations**

Existing waterharvesting authorisations are being converted to water allocations on:

- The Nogoa River from the Theresa Creek junction to the Comet River junction;
- The Mackenzie River from the Comet River junction to the Dawson River junction; and
- Sections of tributaries of the Nogoa and Mackenzie rivers for which access to flows in the above river sections has been defined.

#### **2 Rules for conversion of existing authorisations to water allocations**

The following rules apply for the conversion of existing waterharvesting authorisations to water allocations to establish the details required for the registration of unsupplemented water allocations.

##### **2.1 Location**

The location from which water may be taken under a water allocation is specified as a zone according to the position of the existing authorisation. Descriptions of the zones for the Nogoa and Mackenzie rivers are given in Attachment 2.2.

##### **2.2 Purpose**

The purpose for which water may be taken under a water allocation is specified as either 'agriculture' or 'any'. 'Agriculture' is the nominated purpose for those existing authorisations that are primarily used for agricultural purposes. 'Any' is the nominated purpose for all other uses of water.

##### **2.3 Maximum rate**

With the exception of those authorisations in Table 2 for which the chief executive has previously stated a rate on the existing authorisation as a consequence of the requirements of the Water Resource Plan (WRP), the maximum rate (in litres per second) for taking water is the greater of:

- a) For an authorisation that states a maximum rate, the existing authorised rate; or
- b) For an authorisation that states a pump size, a rate decided by the chief executive using information from Table 1; or

- c) A rate determined by the chief executive based on consideration of a submission on the draft Resource Operations Plan (ROP) about this rate. In consideration of a submission the chief executive will have regard to the existing diversion capacity as at 1 June 2002, and consistency with other authorisations in the same locality. The existing diversion capacity for pumps will be considered at stream flow conditions within 2 metres above the flow conditions for the authorisation.

**Table 1: Pump sizes and rates**

Nominal pump size (mm)	Rate (L/s)		Nominal pump size (mm)	Rate (L/s)
32	7		200	185
40	12		250	250
50	17		300	300
65	30		350	350
80	45		400	430
100	65		500	650
125	90		600–660	1,100
150	115			

*(Note: Multiply litres per second by 0.0864 to convert to megalitres per day)*

**Table 2: Authorisations for which maximum rates previously established**

Authorisation No.	Basis for determining the maximum rate for taking water
51614F	This licence originally authorised a 300 mm submersible pump, which had an operational pumping rate of 450 L/s. An additional 610 mm pump was authorised on the licence on the basis that the licensee agree to the pump rate not exceeding 450 L/s, and only one pump operating at any time.

## 2.4 Flow conditions

The flow conditions under which water may be taken are specified as a rate of passing flow.

The flow conditions are translated from the flow requirements specified on existing waterharvesting authorisations as follows:

- For an existing authorisation with flow conditions of equal to or less than 30 cumec, the flow condition is '2,592 ML/day passing flow'; and
- For an existing authorisation with flow conditions greater than 30 cumec up to 50 cumec, the flow condition is '4,320 ML/day passing flow'.

## 2.5 Volume

The volume for a water allocation comprises two elements – a volumetric limit and a nominal volume.

### 2.5.1 Volumetric limit

The volumetric limit (in megalitres) for conversion of a waterharvesting authorisation is calculated by multiplying the maximum rate for taking water (expressed in megalitres per day) determined in Section 2.3 by the 30<sup>th</sup> percentile water allocation security objective value (expressed in days) given in Table 3.

**Table 3: 30<sup>th</sup> percentile water allocation security objectives and nominal volume conversion factor**

Location for water allocation	Zone	Flow conditions	Water allocation security objective in 30% years	Nominal volume conversion factor
Mackenzie River from the Isaac Mackenzie waterharvesting upstream limit to the Dawson River junction	Mackenzie A Mackenzie B Mackenzie C	2,592 ML/day passing flow	26 days	0.88
	Mackenzie D Mackenzie E	4,320 ML/day passing flow	23 days	0.83
Nogoa and Mackenzie rivers from the Comet Mackenzie waterharvesting upstream limit to the Isaac Mackenzie waterharvesting upstream limit	Mackenzie F Mackenzie G Mackenzie H	2,592 ML/day passing flow	22 days	0.73
	Mackenzie I Mackenzie J Mackenzie K	4,320 ML/day passing flow	17 days	0.69
Nogoa River from the Theresa Creek junction to the Comet Mackenzie waterharvesting upstream limit	Mackenzie L	2,592 ML/day passing flow	12 days	0.65

### 2.5.2 Nominal volume

The nominal volume for a water allocation is determined by sharing the long-term average amount of water expected to be taken by existing authorisations in the relevant water allocation security group.

The nominal volume (in megalitres) for conversion of a waterharvesting authorisation is calculated by multiplying the volumetric limit (in megalitres) determined under Section 2.5.1 by the nominal volume conversion factor given in Table 3.

### 2.6 Water allocation groups

The water allocation group for a water allocation is specified in Table 4. The water allocation group represents a water allocation security objective group specified in the Water Resource Plan (WRP).

**Table 4: Water allocation groups**

Location for water allocation	Zone	Water allocation group	Flow conditions for water allocations
Mackenzie River from the Isaac Mackenzie waterharvesting upstream limit to the Dawson River junction	Mackenzie A Mackenzie B Mackenzie C Mackenzie D Mackenzie E	Class 1A	2,592 ML/day passing flow
		Class 1B	4,320 ML/day passing flow
Nogoa and Mackenzie rivers from the Comet Mackenzie waterharvesting upstream limit to the Isaac Mackenzie waterharvesting upstream limit	Mackenzie F Mackenzie G Mackenzie H Mackenzie I Mackenzie J Mackenzie K	Class 2A	2,592 ML/day passing flow
		Class 2B	4,320 ML/day passing flow
Nogoa River from the Theresa Creek junction to the Comet Mackenzie waterharvesting upstream limit	Mackenzie L	Class 3A	2,592 ML/day passing flow

### 3 Water allocation security objectives

The water allocation security objectives are specified in the WRP.

# **Attachment 5.2C**

## **Nogoa Mackenzie Water Management Area**

### **Rules for conversion of existing area irrigated authorisations to water allocations**

---

#### **1 Locations where existing area-irrigated authorisations are being converted to water allocations**

Existing area irrigated authorisations are being converted to water allocations on the Mackenzie River from the Springton Creek junction to the Dawson River junction.

#### **2 Rules for conversion of existing authorisations to water allocations**

The following rules apply for the conversion of existing area irrigated authorisations to water allocations to establish the details required for the registration of unsupplemented water allocations.

##### **2.1 Location**

The location from which water may be taken under a water allocation is specified as a zone according to the position of the existing authorisation. Descriptions of the zones for the Nogoa and Mackenzie rivers are given in Attachment 2.2.

##### **2.2 Purpose**

The purpose for which water may be taken under a water allocation is specified as either 'agriculture' or 'any'. 'Agriculture' is the nominated purpose for those existing authorisations that are primarily used for agricultural purposes. 'Any' is the nominated purpose for all other uses of water.

##### **2.3 Maximum rate**

The maximum rate (in litres per second) for taking water is the greater of:

- a) For an authorisation that states a maximum rate, the existing authorised rate; or
- b) A rate of 1 litre per second per hectare for the area stated on the existing authorisation; or
- c) A rate determined by the chief executive based on consideration of a submission on the draft Resource Operations Plan (ROP) about this rate. In consideration of a submission the chief executive will have regard to the existing diversion capacity as at 1 June 2002, and consistency with other authorisations in the same locality.

## 2.4 Volume

The volume for a water allocation comprises two elements – a volumetric limit and a nominal volume.

### 2.4.1 Volumetric limit

The volumetric limit (in megalitres) for conversion of an area-irrigated authorisation is calculated by multiplying the area (in hectares) stated on the existing authorisation by 6.

### 2.4.2 Nominal volume

The nominal volume for a water allocation is determined by sharing the long-term average annual amount of water expected to be taken by existing authorisations in the relevant water allocation security group.

The nominal volume (in megalitres) for conversion of an area-irrigated authorisation is calculated by multiplying the volumetric limit (in megalitres) determined under Section 2.4.1 by the nominal volume conversion factor given in Table 1.

**Table 1: Nominal volume conversion factor**

Location for water allocation	Zone	Flow conditions	Nominal volume conversion factor
Mackenzie River from the Springton Creek junction to the Dawson River junction	Mackenzie A	No flow condition, and 9 ML/day passing flow	0.88

## 2.5 Flow conditions

The flow conditions under which water may be taken are specified as a rate of passing flow translated from the flow requirements specified on the existing authorisation.

## 2.6 Water allocation groups

The water allocation group for a water allocation is specified in Table 2. The water allocation group represents a water allocation security objective group specified in the Water Resource Plan (WRP).

**Table 2: Water allocation group**

Location for water allocation	Zone	Water allocation group	Flow conditions for water allocations
Mackenzie River from the Springton Creek junction to the Dawson River junction	Mackenzie A	Class 4C	No flow condition, and 9 ML/day passing flow

## 3 Water allocation security objectives

The water allocation security objectives are specified in the WRP.

# Attachment 5.2D

## Nogoa Mackenzie Water Management Area

### Amending existing waterharvesting authorisations

Waterharvesting authorisations on the Nogoa River from the Fairbairn Dam pond downstream to the Theresa Creek junction remain as water licences under this Resource Operations Plan (ROP). These licences are not being converted to water allocations because the performance of waterharvesting in this reach does not have a specified water allocation security objective in the Water Resource Plan. Waterharvesting in this reach is permitted only when Fairbairn Dam overflows at greater than 30 cumec, which occurs in fewer than 30 per cent of years.

These waterharvesting licences will be amended for consistency with the operating rules given in Attachment 5.2F and to specify a volumetric limit and a maximum rate for taking water.

#### 1 Locations where existing waterharvesting authorisations will be amended

Existing waterharvesting licences will be amended on the Nogoa River from the upstream limit of Fairbairn Dam to the Theresa Creek junction (Zones Mackenzie N and M).

#### 2 Details for amendment of existing authorisations

Amendments will be made to existing water licences as follows:

##### 2.1 Location

The location from which water may be taken under a water licence will be amended to a zone according to the position of the existing authorisation. Descriptions of the zones for the Nogoa and Mackenzie rivers are given in Attachment 2.2.

##### 2.2 Maximum rate

A maximum rate (in litres per second) for taking water under a water licence will be stated or amended if stated on the existing authorisation. The maximum rate will be the greater of:

- a) For an authorisation that states a maximum rate, the existing authorised rate; or
- b) For an authorisation that states a pump size, a rate decided by the chief executive using information from Table 1; or
- c) A rate determined by the chief executive for an authorisation having regard to the existing diversion capacity as at 1 June 2002, and consistency with other authorisations in the same locality. The existing diversion capacity for pumps will be considered at stream flow conditions within 2 metres above the flow conditions for the authorisation.

**Table 1: Pump sizes and rates**

Nominal pump size (mm)	Rate (L/s)		Nominal pump size (mm)	Rate (L/s)
32	7		200	185
40	12		250	250
50	17		300	300
65	30		350	350
80	45		400	430
100	65		500	650
125	90		600–660	1,100
150	115			

*(Note: Multiply litres per second by 0.0864 to convert to megalitres per day)*

### 2.3 Volume

The volume for a water licence will state a volumetric limit.

The volumetric limit (in megalitres) is calculated by multiplying the maximum rate for taking water (expressed in megalitres per day) determined in Section 2.2 by 6 days. The performance indicators show that volume would occur in less than the 30<sup>th</sup> percentile wettest year based on the simulated diversion estimated to occur in this locality.

### 2.4 Operating rules

The flow conditions for all existing waterharvesting authorisations will be respecified as '2,592 ML/day passing flow' for consistency with the operating rules in the ROP. 2,592 ML/day is equal to 30 cumec, the value stated on existing authorisations.

The terms and conditions about the arrangements for the taking of water stated on existing licences will be replaced by reference to the operating rules given in Attachment 5.2F.

## Attachment 5.2E

## Nogoa Mackenzie Water Management Area

### Operating rules for water allocations and water licences with 2,592 and 4,320 ML/day passing flow conditions

These operating rules apply to water allocations and water licences with 2,592 and 4,320 ML/day passing flow conditions in the Nogoa Mackenzie Water Management Area, from the upstream limit of Fairbairn Dam to the Dawson River junction.

#### **1 Water year**

The water year is from 1 July to 30 June the following year.

#### **2 Location from which water may be taken**

The location from which water may be taken is described on each water allocation and water licence as a zone. Descriptions of zones for the Nogoa and Mackenzie rivers are given in Attachment 2.2.

#### **3 Purpose for which water may be taken**

The purpose for which water may be taken is stated on each water allocation or water licence. For the purpose of 'agriculture', water may be taken for agricultural purposes. For the purpose of 'any', water may be taken for any purpose.

#### **4 Maximum volume of water taken**

The maximum volume of water taken in any water year must not exceed the volumetric limit stated on a water allocation or water licence.

#### **5 Maximum rate for taking water**

The maximum rate that water may be taken is the maximum rate stated on a water allocation or water licence, averaged over any continuous 48-hour period.

Under the provisions of Chapter 8, the chief executive may change the specified continuous period having regard to water sharing between allocation holders and the objectives of the Water Resource Plan.

#### **6 Flow conditions under which water may be taken**

The passing flow conditions stated on a water allocation or water licence is the stream flow nominally required to pass downstream while water is being taken under the water allocation or water licence.

The chief executive will determine when the passing flow conditions exist and when water may be taken under arrangements given in Sections 7 and 8. A period of time during which

water may be taken is referred to as an announced period.

## **7 Announced periods for taking water**

The chief executive will notify water allocation and water licence holders and the Resource Operations Licence (ROL) holder of the start and of the end of an announced period during which water may be taken.

Water may only be taken during announced periods, unless the chief executive has authorised an individual water allocation holder to take water outside of an announced period.

In some circumstances a water allocation holder may experience difficulty taking water during all or part of an announced period because of the characteristics of the flow event and the flow management location where the passing flow conditions are assessed under Section 8. Under these circumstances the chief executive may authorise a water allocation holder to take water outside an announced period under alternative arrangements if the chief executive is satisfied that:

- No significant adverse impacts on other water users are expected; and
- The authorisation given does not exceed the announced period applying to other water allocations in the same locality.

## **8 Determining announced periods for taking water**

Subject to the requirements of the first post-winter flow management strategies in Section 9, for each management reach in Table 1 the chief executive will estimate the start and the end of a period during which the stream flow is estimated to exceed the passing flow conditions for each water allocation and water licence group. The stream flow will be assessed at the flow management locations in Table 1.

The announced period is subject to the following conditions:

- The chief executive may delay the notification of the start of an announced period for taking water up to a maximum of 24 hours from the estimated time when the passing flow conditions exist, provided the notification of the end of the announced period is extended by a similar time;
- The typical duration of an announced period should not vary by more than 12 hours from the total estimated time that the passing flows exist. The chief executive may extend a subsequent announced period to adjust for any variations in excess of 12 hours; and
- The chief executive may use information about stream flow other than at the flow measurement locations in Table 1 to determine an announced period.

**Table 1: Management reaches and flow management locations for water allocations and water licences with 2,592 and 4,320 ML/day passing flow conditions**

Management reach	Management reach description	Flow management location
<b>Zones: Mackenzie A, B.</b>	Coolmaringa Gauging Station to Dawson River junction	Coolmaringa Gauging Station
<b>Zones: Mackenzie C, D, E.</b>	Isaac Mackenzie waterharvesting upstream limit to Coolmaringa Gauging Station	Tartus Weir tailwater
<b>Zones: Mackenzie F, G.</b>	Effective upstream limit of Bingegang Weir to Isaac Mackenzie waterharvesting upstream limit	Bingegang Weir tailwater
<b>Zones: Mackenzie H.</b>	Bedford Weir to effective upstream limit of Bingegang Weir	Bedford Weir tailwater
<b>Zones: Mackenzie I, J, K.</b>	Comet Mackenzie waterharvesting upstream limit to Bedford Weir	Nogoa River and Comet River junction
<b>Zones: Mackenzie L.</b>	Theresa Ck junction to Comet Mackenzie waterharvesting upstream limit	Duckponds Gauging Station
<b>Zones: Mackenzie M, N.</b>	Upstream limit of Fairbairn Dam to Theresa Creek junction	Fairbairn Dam tailwater

## 9 Environmental flow management rules

### 9.1 First post-winter flow management strategy for waterharvesting for the Nogoa River upstream of the Comet Mackenzie waterharvesting upstream limit (Zones: Mackenzie L, M, N)

The following first post-winter flow management strategy applies to waterharvesting upstream of the Comet Mackenzie waterharvesting upstream limit (Zones: Mackenzie L, M, N).

The first post-winter flow management strategy commences at the earlier of:

- Activation of the Node 11 (Carnangarra) first post-winter flow management strategy for the Nogoa Mackenzie Water Supply Scheme; or
- 1 October.

The first post-winter flow management strategy ends at the earlier of:

- 4 days of flow greater than 2,592 ML/day passing Duckponds Gauging Station since the commencement of the strategy; or
- Finalisation of the Node 11 (Carnangarra) first post-winter flow management strategy for the Nogoa Mackenzie Water Supply Scheme; or
- 30 April.

For the full duration of the first post-winter flow management strategy, the chief executive will apply a 4,320 ML/day flow condition for all announced periods for waterharvesting.

**9.2 First post-winter flow management strategy for waterharvesting for the Nogoia and Mackenzie rivers between the Comet Mackenzie waterharvesting upstream limit and Bedford Weir (Zones: Mackenzie I, J, K)**

The following first post-winter flow management strategy applies to waterharvesting between the Comet Mackenzie waterharvesting upstream limit and Bedford Weir (Zones: Mackenzie I, J, K).

The first post-winter flow management strategy commences at the earlier of:

- Activation of the Node 11 (Carnangarra) first post-winter flow management strategy for the Nogoia Mackenzie Water Supply Scheme; or
- 1 October.

The first post-winter flow management strategy ends at the earlier of:

- 6 days of flow greater than 2,592 ML/day passing at the junction of the Nogoia and Comet Rivers since the commencement of the strategy; or
- Finalisation of the Node 11 (Carnangarra) first post-winter flow management strategy for the Nogoia Mackenzie Water Supply Scheme; or
- 30 April.

For the full duration of the first post-winter flow management strategy, the chief executive will apply a 4,320 ML/day flow condition for all announced periods for waterharvesting.

**9.3 First post-winter flow management strategy for waterharvesting for the Mackenzie River between Bedford Weir and the Isaac Mackenzie waterharvesting upstream limit (Zones: Mackenzie F, G, H)**

The following first post-winter flow management strategy applies to waterharvesting between Bedford Weir and the Isaac Mackenzie waterharvesting upstream limit (Zones: Mackenzie F, G, H).

The first post-winter flow management strategy commences at the earlier of:

- Activation of the Node 10 (Bingegang) first post-winter flow management strategy for the Nogoia Mackenzie Water Supply Scheme; or
- 1 October.

The first post-winter flow management strategy ends at the earlier of:

- 6 days of flow greater than 2,592 ML/day passing Bingegang Weir since the commencement of the strategy; or
- Finalisation of the Node 10 (Bingegang) first post-winter flow management strategy for the Nogoia Mackenzie Water Supply Scheme; or
- 30 April.

For the full duration of the first post-winter flow management strategy, the chief executive will apply a 4,320 ML/day flow condition for all announced periods for waterharvesting.

#### **9.4 First post-winter flow management strategy for waterharvesting for the Mackenzie River between the Isaac Mackenzie waterharvesting upstream limit and the Dawson River junction (Zones: Mackenzie A, B, C, D, E)**

The following first post-winter flow management strategy applies to waterharvesting between the Isaac Mackenzie waterharvesting upstream limit and the Dawson River junction (Zones: Mackenzie A, B, C, D, E).

The first post-winter flow management strategy commences at the earlier of:

- Activation of the Node 10 (Bingegang) first post-winter flow management strategy for the Nogoia Mackenzie Water Supply Scheme; or
- 1 October.

The first post-winter flow management strategy ends at the earlier of:

- 8 days of flow greater than 2,592 ML/day passing Coolmaringa Gauging Station since the commencement of the strategy; or
- Finalisation of the Node 10 (Bingegang) first post-winter flow management strategy for the Nogoia Mackenzie Water Supply Scheme; or
- 30 April.

For the full duration of the first post-winter flow management strategy, the chief executive will apply a 4,320 ML/day flow condition for all announced periods for waterharvesting.

#### **10 Assessment of quantity of unsupplemented water taken**

For the assessment of the quantity of unsupplemented water taken under a water allocation or water licence:

- A water allocation or water licence holder must advise the chief executive prior to taking unsupplemented water;
- A water allocation or water licence holder must provide recordings of water taken to the chief executive;
- Only water taken during announced periods may be taken as unsupplemented water unless otherwise authorised by the chief executive under Section 7;
- The chief executive will advise the Resource Operations Licence holder for the Nogoia Mackenzie Water Supply Scheme of the meter readings and the approved quantities of unsupplemented water taken within 7 business days of the conclusion of announced periods for all management reaches in the Nogoia Mackenzie Water Management Area; and
- Any water taken that is not in accordance with these rules for unsupplemented water and taken from within the limits of the Nogoia Mackenzie Water Supply Scheme will be treated as supplemented water.

#### **11 Seasonal water assignment rules**

A water allocation holder may apply under Section 142 of the Water Act for a seasonal water assignment for the water year in which the application is made.

Seasonal water assignment of water licences in the Nogoia Mackenzie Water Management Area is not permitted.

An application for a seasonal assignment of a water allocation located in zone Mackenzie A, B, C, D, or E will be approved for:

- All or part of that portion of the volumetric limit for the water allocation that has not been taken in the current water year; if
- The water under seasonal assignment is taken from within zone Mackenzie A, B, C, D or E.

An application for a seasonal assignment of a water allocation located in zone Mackenzie F, G, H, I, J or K will be approved for:

- All or part of that portion of the volumetric limit for the water allocation that has not been taken in the current water year; if
- The water under seasonal assignment is taken from within zone Mackenzie F, G, H, I, J or K.

An application for a seasonal assignment of a water allocation located in zone Mackenzie L will be approved for:

- All or part of that portion of the volumetric limit for the water allocation that has not been taken in the current water year; and
- The water under seasonal assignment is taken from within zone Mackenzie L.

On approval the chief executive will issue a water permit for the seasonal assignment. The conditions for the water permit will include:

- A maximum rate for taking water in the same proportion to the seasonal assignment volume as the maximum rate for taking water is to the volumetric limit stated on the water allocation under seasonal assignment; and
- A passing flow condition the same as the water allocation under seasonal assignment.

On approval of the water permit, the chief executive will reduce the volumetric limit for the current water year and the maximum rate for taking water for the remainder of the current water year for the water allocation under seasonal assignment by the volume and maximum rate specified for the water permit.

The holder of the seasonal assignment water permit must be a holder of a development permit for works used to take the seasonally assigned water.

## **12 Procedures**

Details of procedures associated with the implementation of these operating rules may be obtained from the chief executive.

# **Attachment 5.2G**

## **Nogoa Mackenzie Water Management Area**

### **Operating rules for water allocations with up to 9 ML/day passing flow conditions**

---

These operating rules apply to water allocations with up to 9 ML/day passing flow conditions in the Nogoa Mackenzie Water Management Area, from the Springton Creek junction to the Dawson River junction.

#### **1 Water year**

The water year is from 1 July to 30 June the following year.

#### **2 Location from which water may be taken**

The location from which water may be taken for a water allocation with a passing flow condition is described on the water allocation as a zone.

The location from which water may be taken for a water allocation without a passing flow condition is specified as two components on a water allocation. The first component is the zone specification. The second component is the position specification, which is the AMTD position along the river within the zone. The holders of these water allocations may take water below the cease to flow level of a waterhole at the AMTD location on the water allocation.

Descriptions of zones for the Nogoa and Mackenzie rivers are given in Attachment 2.2.

#### **3 Purpose for which water may be taken**

The purpose for which water may be taken is stated on each water allocation. For the purpose of ‘agriculture’, water may be taken for agricultural purposes. For the purpose of ‘any’, water may be taken for any purpose.

#### **4 Maximum volume of water taken**

The maximum volume of water taken in any water year must not exceed the volumetric limit stated on a water allocation.

#### **5 Maximum rate for taking water**

The maximum rate that water may be taken is the maximum rate stated on a water allocation, averaged over any continuous 48-hour period.

Under the provisions of Chapter 8, the chief executive may amend the specified continuous period having regard to water sharing between allocation holders and the objectives of the Water Resource Plan.

## 6 Flow conditions under which water may be taken

The passing flow conditions stated on a water allocation is the stream flow nominally required to pass downstream while water is being taken under the water allocation.

For water allocations with stated passing flow conditions, the chief executive will determine those periods when the passing flow conditions exist and when water may be taken by assessment of stream flows at the locations in Table 1. The chief executive will notify water allocation holders when the taking of water is permitted.

For water allocations without stated passing flow conditions, the limitations for taking water from waterholes given in Section 7 apply.

**Table 1: Management reaches and flow management locations for water allocations with 9 ML/day passing flow conditions**

Management reach	Flow management location
Zones: Mackenzie A	Mackenzie River at the Springton Creek junction

## 7 Drawdown conditions for waterholes

The following conditions apply to holders of water allocations without passing flow conditions who may take water below the cease to flow level of a waterhole:

- A water allocation holder must advise the chief executive prior to taking water from a waterhole more than 0.5 metres below the cease to flow level;
- A water allocation holder must keep a daily record of the level of a waterhole below cease to flow level when taking water from a waterhole more than 0.5 metres below the cease to flow level;
- The chief executive may limit the water that may be taken under a water allocation from a waterhole by notifying the holder of a water allocation if the chief executive is satisfied that limitations are necessary for protection of the natural ecosystem, or sharing the available water at times of water shortage. Limits on the water that may be taken may include any one or more of the following:
  - The times when water may be taken by a water allocation holder;
  - The purpose for which water may be taken; and
  - The volume of water that may be taken by a water allocation holder.

## 8 First post-winter flow management strategy

First post-winter flow management strategies do not apply.

## 9 Water allocation holder to record quantity of water taken

Each water allocation holder must record the quantity of water taken and provide the chief executive with those records.

## 10 Seasonal water assignment rules

A water allocation holder may apply under Section 142 of the Water Act for a seasonal water assignment for the water year in which the application is made.

### 10.1 Water allocations with 9 ML/day passing flow conditions

An application for a seasonal assignment of a water allocation with a 9 ML/day passing flow condition will be approved for:

- All or part of that portion of the volumetric limit for the water allocation that has not been taken in the current water year; if
- The water under seasonal assignment is taken from within zone Mackenzie A.

On approval the chief executive will issue a water permit for the seasonal assignment. The conditions for the water permit will include:

- A maximum rate for taking water in the same proportion to the seasonal assignment volume as the maximum rate for taking water is to the volumetric limit stated on the water allocation under seasonal assignment; and
- A passing flow condition of 9 ML/day.

On approval of the water permit, the chief executive will reduce the volumetric limit for the current water year and the maximum rate for taking water for the remainder of the current water year for the water allocation under seasonal assignment by the volume and maximum rate specified for the water permit.

The holder of the seasonal assignment water permit must be a holder of a development permit for works used to take the seasonally assigned water.

### 10.2 Water allocations with no passing flow conditions

An application for a seasonal assignment for a water allocation with no passing flow conditions will be approved for:

- All or part of the portion of the volumetric limit for the water allocation that has not been taken in the current water year; if
- The water under seasonal assignment will be taken from the same waterhole indicated by the AMTD position specified on the water allocation.

On approval the chief executive will issue a water permit for the seasonal assignment. The conditions specified for the water permit will include:

- A maximum rate for taking water in the same proportion to the seasonal assignment volume as the maximum rate for taking water is to the volumetric limit stated on the water allocation under seasonal assignment; and
- No passing flow condition.

On approval of the water permit, the chief executive will reduce the volumetric limit for the current water year and the maximum rate for taking water for the remainder of the current water year for the water allocation under seasonal assignment by the volume and maximum rate specified for the water permit.

The holder of the seasonal assignment water permit must be a holder of a development permit for works used to take the seasonally assigned water.

## 11 Procedures

Details of procedures associated with the implementation of these operating rules are

available from the chief executive.

# Attachment 5.2H

## Nogoa Mackenzie Water Management Area

### Water allocation change rules

#### 1 Permitted changes

Applications for the following changes to a water allocation will be approved. On approval a change certificate will be issued by the chief executive, which may be lodged with the registrar of water allocations.

##### 1.1 Location

###### 1.1.1 Water allocations with 2,592 or 4,320 ML/day passing flow conditions

A change to the location of a water allocation with a 2,592 or 4,320 ML/day passing flow condition from any one of the following zones to any other of those zones:

- Mackenzie A;
- Mackenzie B;
- Mackenzie C;
- Mackenzie D; or
- Mackenzie E.

A change to the location of a water allocation with a 2,592 or 4,320 ML/day passing flow condition from any one of the following zones to any other of those zones:

- Mackenzie F;
- Mackenzie G;
- Mackenzie H;
- Mackenzie I;
- Mackenzie J; or
- Mackenzie K.

###### 1.1.2 Water allocations with no flow conditions

A change to the AMTD position specification for the location of a water allocation with no flow conditions to a new AMTD position on the same waterhole that applies to the allocation being changed.

A change to remove the AMTD specification of the location of a water allocation with no flow conditions. A passing flow condition of 9 ML/day will be set for the changed water allocation.

##### 1.2 Purpose

A change to the purpose of a water allocation from 'any' to 'agriculture' or from 'agriculture' to 'any'.

### 1.3 Amalgamation or subdivision

A change to subdivide a water allocation into two or more water allocations, provided:

- The volumes and the maximum rates for each of the new water allocations are in the same proportion as the volumes and the maximum rates for the original water allocation; and
- The sum of the volumes and the maximum rates for the new water allocations is the same as the volumes and the maximum rate for the original allocation.

A change to amalgamate two or more water allocations with the same location and the same flow condition specifications, provided:

- The volumes and the maximum rate for the new water allocation are the combined volumes and the combined maximum rates specified for the original water allocations.

A change to amalgamate two or more water allocations with AMTD position specifications that apply to the same waterhole, provided:

- The volumes and rate for the new water allocation are the combined volumes and the combined rates of the original water allocations; and
- The AMTD specification for the new water allocation applies to the same waterhole as the original water allocations.

## 2 Prohibited changes

The following changes are prohibited changes.

### 2.1 Location

For a water allocation with a 2,592 ML/day or 4,320 ML/day passing flow condition, a change to a location that is not:

- Zone Mackenzie A, B, C, D, E, F, G, H, I, J, K, or L in the Nogoia Mackenzie Water Management Area; or
- Zone Fitzroy A, B, C, D, or E in the Fitzroy Water Management Area.

For a water allocation with a 9 ML/day passing flow condition or no flow condition, a change to a location that is not:

- Zone Mackenzie A in the Nogoia Mackenzie Water Management Area; or
- Zone Fitzroy D or Fitzroy E in the Fitzroy Water Management Area.

### 2.2 Purpose

A change to a purpose that is not 'agriculture' or 'any'.

### 2.3 Volume

A change to the volume of a water allocation that is not a consequence of a change to another attribute of a water allocation.

### 2.4 Rate

A change to the maximum rate of a water allocation that is not a consequence of a change to another attribute of a water allocation.

## **2.5 Supply of water under a resource operations licence**

A change to a water allocation that would result in a water allocation being managed under a Resource Operations Licence.

## **2.6 Other**

A change to a water allocation that requires an amendment to this ROP, other than an amendment provided for in Chapter 8.

## **3 Application for change under Section 130 of the Water Act**

If a water allocation holder wishes to apply for a change to a water allocation that is not permitted under Section 1 above, and not prohibited under Section 2 above, then application may be made under Section 130 of the Water Act for the change.

The chief executive will deal with applications made under Section 130 of the Water Act, in accordance with the Water Act. That process is as follows:

- Notice of the application is published in local newspapers. The notice includes information about where the application can be inspected and invites submissions from the public on the application.
- The chief executive determines if the application should be approved having regard to the potential impact on a range of interests including other entitlement holders and aquatic ecosystems.
- If the chief executive approves the application, the chief executive will issue a change certificate that may be lodged with the registrar of water allocations.
- If the chief executive refuses the application, the Water Act provides for an appeal process.

## **4 Registration of change**

If an application to change a water allocation is approved, the chief executive will issue a change certificate. The water allocation holder may lodge the change certificate with the registrar of water allocations who will change the water allocation on the water allocation register.

# Attachment 5.3A

## Fitzroy Water Management Area

### Details of conversions to water allocations

Water allocation number	Family name/ Company	Given names	Tenancy type	Tenancy comments	Share of water allocation	Location (AMTD km)	Purpose	Nominal volume (ML/water year)	Volumetric limit (ML/ water year)	Maximum rate (L/s)	Flow conditions	Water allocation group	Converting authorisation

TTE: Trustee

Note that Attachment 5.3A shows details of relevant authorisations supplied through the Fitzroy Water Management Area as at **13 November 2003**. Any changes that occur after 13 November 2003, for example, transfers of a listed authorisation to another person, or from amalgamations or subdivisions of listed authorisations, will be dealt with through standard procedures established to register changes to the water allocation register

# Attachment 5.3B

## Fitzroy Water Management Area

### Rules for conversion of existing waterharvesting authorisations to water allocations

#### 1 Locations where existing waterharvesting authorisations are being converted to water allocations

Existing waterharvesting authorisations are being converted to water allocations on:

- The Fitzroy River from the Dawson River junction to the Fitzroy Barrage; and
- Sections of tributaries of the Fitzroy River for which access to flows in the above river section has been defined.

#### 2 Rules for conversion of existing authorisations to water allocations

The following rules apply for the conversion of existing waterharvesting authorisations to water allocations to establish the details required for the registration of unsupplemented water allocations.

##### 2.1 Location

The location from which water may be taken under a water allocation is specified as a zone according to the position of the existing authorisation. Descriptions of the zones for the Fitzroy River are given in Attachment 2.3.

##### 2.2 Purpose

The purpose for which water may be taken under a water allocation is specified as either 'agriculture' or 'any'. 'Agriculture' is the nominated purpose for those existing authorisations that are primarily used for agricultural production. 'Any' is the nominated purpose for all other uses of water.

##### 2.3 Maximum rate

With the exception of those authorisations in Table 2 for which the chief executive has previously stated a rate on the existing authorisation as a consequence of the requirements of the Water Resource Plan (WRP), the maximum rate (in litres per second) for taking water is the greater of:

- a) For an authorisation that states a maximum rate, the existing authorised rate; or
- b) For an authorisation that states a pump size, a rate decided by the chief executive using information from Table 1; or
- c) A rate determined by the chief executive based on consideration of a submission on the draft Resource Operations Plan (ROP) about this rate. In consideration of a submission the chief executive will have regard to the existing diversion capacity as at 1 June 2002, and consistency with other authorisations in the same locality. The existing diversion capacity for pumps will be considered at stream flow conditions within 2 metres above the flow conditions for the authorisation.

**Table 1: Pump sizes and rates**

Nominal pump size (mm)	Rate (L/s)		Nominal pump size (mm)	Rate (L/s)
32	7		200	185
40	12		250	250
50	17		300	300
65	30		350	350
80	45		400	430
100	65		500	650
125	90		600–660	1,100
150	115			
<i>(Note: Multiply litres per second by 0.0864 to convert to megalitres per day)</i>				

**Table 2: Authorisations for which maximum rates previously established**

Authorisation No.	Basis for determining the maximum rate for taking water
57500U	This licence originally authorised a 400 mm turbine pump with a maximum pumping rate of 350 L/s. The authorised pump size was increased to 600 mm in 2002 on the basis the licensee agree to a maximum pumping rate of 430 L/s, which is consistent with the rate in Table 1.

## 2.4 Flow conditions

The flow conditions under which water may be taken are specified as a rate of passing flow.

The flow conditions are translated from the flow requirements specified on existing waterharvesting authorisations. For existing authorisations with flow conditions of equal to or less than 30 cumec, the flow condition is ‘2,592 ML/day passing flow’.

## 2.5 Volume

The volume for a water allocation comprises two elements – a volumetric limit and a nominal volume.

### 2.5.1 Volumetric limit

The volumetric limit (in megalitres) for conversion of a waterharvesting authorisation is calculated by multiplying the maximum rate for taking water (expressed in megalitres per day) determined in Section 2.3 by the 30<sup>th</sup> percentile water allocation security objective value (expressed in days) given in Table 3.

**Table 3: 30<sup>th</sup> percentile water allocation security objectives and nominal volume conversion factor**

Location for water allocation	Zone	Flow conditions	Water allocation security objective in 30% years	Nominal volume conversion factor
Fitzroy River from the Dawson River junction to the Fitzroy Barrage	Fitzroy A Fitzroy B Fitzroy C Fitzroy D Fitzroy E	2,592 ML/day passing flow	72 days	0.75

### 2.5.2 Nominal volume

The nominal volume for a water allocation is determined by sharing the long-term average amount of water expected to be taken by existing authorisations in the relevant water allocation security group.

The nominal volume (in megalitres) for conversion of a waterharvesting authorisation is calculated by multiplying the volumetric limit (in megalitres) determined under Section 2.5.1 by the nominal volume conversion factor given in Table 3.

### 2.6 Water allocation groups

The water allocation group for a water allocation is specified in Table 4. The water allocation group represents a water allocation security objective group specified in the Water Resource Plan (WRP).

**Table 4: Water allocation groups**

Location for water allocation	Zone	Water allocation group	Flow conditions for water allocations
Fitzroy River from the Dawson River junction to the Fitzroy Barrage	Fitzroy A Fitzroy B Fitzroy C Fitzroy D Fitzroy E	Class 5A	2,592 ML/day passing flow

## 3 Water allocation security objectives

The water allocation security objectives are specified in the WRP.

# Attachment 5.3C

## Fitzroy Water Management Area

### Rules for conversion of existing authorisations other than waterharvesting to water allocations

#### 1 Locations where existing authorisations are being converted to water allocations

Existing authorisations other than for waterharvesting are being converted to water allocations on the Fitzroy River from the Dawson River junction to the upstream limit of Eden Bann Weir.

#### 2 Rules for conversion of existing authorisations to water allocations

The following rules apply for the conversion of existing authorisations other than for waterharvesting to water allocations to establish the details required for the registration of unsupplemented water allocations. The conversion details for each existing authorisation are given in Attachment 5.3A.

##### 2.1 Location

The location from which water may be taken under a water allocation is specified as a zone according to the position of the existing authorisation. Descriptions of the zones for the Fitzroy River are given in Attachment 2.3.

##### 2.2 Purpose

The purpose for which water may be taken under a water allocation is specified as either 'agriculture' or 'any'. 'Agriculture' is the nominated purpose for those existing authorisations that are primarily used for agricultural purposes. 'Any' is the nominated purpose for all other uses of water.

##### 2.3 Maximum rate

The maximum rate (in litres per second) for taking water for conversion of existing area irrigated authorisations is the greater of:

- For an authorisation that states a maximum rate, the existing authorised rate; or
- A rate of 1 litre per second per hectare for the area stated on the existing authorisation; or
- A rate determined by the chief executive based on consideration of a submission on the draft Resource Operations Plan (ROP) about this rate. In consideration of a submission the chief executive will have regard to the existing diversion capacity as at 1 June 2002, and consistency with other authorisations in the same locality.

The maximum rate for taking water in converting existing water licence number 48364U (for industrial and mining purposes) has been set at 8 litres per second.

##### 2.4 Volume

The volume for a water allocation comprises two elements a volumetric limit and a nominal

volume.

#### 2.4.1 Volumetric limit

The volumetric limit (in megalitres) for conversion of an area irrigated authorisation is calculated by multiplying the area (in hectares) stated on the existing authorisation by 6.

The volumetric limit for the water allocation converted from existing water licence number 48364U (for industrial and mining purposes) is 45 megalitres, the same value as stated on the existing authorisation.

#### 2.4.2 Nominal volume

The nominal volume for a water allocation is determined by sharing the long-term average annual amount of water expected to be taken by existing authorisations in the relevant water allocation security group.

The nominal volume (in megalitres) for conversion of an area-irrigated authorisation is calculated by multiplying the volumetric limit (in megalitres) determined under Section 2.4.1 by the nominal volume conversion factor given in Table 1.

**Table 1: Nominal volume conversion factors**

Location for water allocation	Zone	Flow conditions	Nominal volume conversion factor
Fitzroy River from the Dawson River junction to the upstream limit of Eden Bann Weir	Fitzroy D Fitzroy E	No flow condition	0.96
		9 ML/day passing flow	0.87
		260 ML/day passing flow	0.73

#### 2.5 Flow conditions

The flow conditions under which water may be taken are specified as a rate of passing flow.

The flow conditions are translated from the flow requirements specified on existing authorisations as follows:

- a) For an existing authorisation with no stated flow conditions, a flow condition is not specified; or
- b) For an existing authorisation with a flow condition of up to 250 litres per second, the flow condition is '9 megalitres per day passing flow'; or
- c) For an existing authorisation with a flow condition of 3 cumec, the flow condition will be '260 megalitres per day passing flow'.

#### 2.6 Water allocation groups

The water allocation group for a water allocation is specified in Table 2. The water allocation group represents a water allocation security objective group specified in the Water Resource Plan (WRP).

**Table 2: Water allocation groups**

Location for water allocation	Zone	Water	Flow conditions for
-------------------------------	------	-------	---------------------

		<b>allocation group</b>	<b>water allocations</b>
Fitzroy River from the Dawson River junction to the upstream limit of Eden Bann Weir	Fitzroy D Fitzroy E	Class 6C	No flow condition, and 9 ML/day passing flow
Fitzroy River from the Dawson River junction to the upstream limit of Eden Bann Weir	Fitzroy D Fitzroy E	Class 7D	260 ML/day passing flow

### **3 Water allocation security objectives**

The water allocation security objectives are specified in the WRP.

## Attachment 5.3D

### Fitzroy Water Management Area

# **Attachment 5.3E**

## **Fitzroy Water Management Area**

### **Operating rules for water allocations with 2,592 and 4,320 ML/day passing flow conditions**

These operating rules apply to water allocations with 2,592 and 4,320 ML/day passing flow conditions in the Fitzroy Water Management Area, from the Dawson River junction to the Fitzroy Barrage.

#### **1 Water year**

The water year is from 1 July to 30 June the following year.

#### **2 Location from which water may be taken**

The location from which water may be taken is described on each water allocation as a zone. Descriptions of the zones for the Fitzroy River are given in Attachment 2.3.

#### **3 Purpose for which water may be taken**

The purpose for which water may be taken is stated on each water allocation. For the purpose of 'agriculture', water may be taken for agricultural purposes. For the purpose of 'any', water may be taken for any purpose.

#### **4 Maximum volume of water taken**

The maximum volume of water taken in any water year must not exceed the volumetric limit stated on a water allocation.

#### **5 Maximum rate for taking water**

The maximum rate that water may be taken is the maximum rate stated on a water allocation, averaged over any continuous 72-hour period.

Under the provisions of Chapter 8, the chief executive may amend the specified continuous period having regard to water sharing between allocation holders and the objectives of the Water Resource Plan.

#### **6 Flow conditions under which water may be taken**

The passing flow conditions stated on a water allocation is the stream flow nominally required to pass downstream while water is being taken under the water allocation.

The chief executive will determine when the passing flow conditions exist and when water may only be taken under arrangements given in Sections 7 and 8. A period of time during which water may be taken is referred to as an announced period.

## 7 Announced periods for taking water

The chief executive will notify water allocation holders and the Resource Operations Licence (ROL) holders of the start and of the end of an announced period during which water may be taken.

Water may be taken only during announced periods.

## 8 Determining announced periods for taking water

Subject to the requirements of the first post-winter flow management strategies in Section 9, for each management reach in Table 1 the chief executive will estimate the start and the end of a period during which the stream flow is estimated to exceed the passing flow conditions for each water allocation group. The stream flow will be assessed at the flow management location in Table 1.

The announced period is subject to the following conditions:

- The chief executive may delay the notification of the start of an announced period for taking water up to a maximum of 72 hours from the estimated time when the passing flow conditions exist, provided the notification of the end of the announced period is extended by a similar time;
- The typical duration of an announced period should not vary by more than 48 hours from the total estimated time that the passing flows exist. The chief executive may extend a subsequent announced period to adjust for any variations in excess of 48 hours; and
- The chief executive may use information about stream flow other than at the flow measurement location in Table 1 to determine an announced period.

**Table 1: Management reaches and flow management locations for water allocations with 2,592 and 4,320 ML/day passing flow conditions**

Management reach	Management reach description	Flow management location
Zones: Fitzroy A, B, C, D, E	Dawson River junction to Fitzroy Barrage	Eden Bann Weir tailwater

## 9 Environmental flow management rules

### 9.1 First post-winter flow management strategy for waterharvesting in the Fitzroy Water Management Area (Zones: Fitzroy A, B, C, D, E.)

The following first post-winter flow management strategy applies to waterharvesting in the Fitzroy Water Management Area (Zones: Fitzroy A, B, C, D, E).

The first post-winter flow management strategy commences on 1 October.

The first post-winter flow management strategy ends at the earlier of:

- A total volume of 90,000 ML has passed Eden Bann Weir since the flow first exceeded 4,320 ML/day (50 cumec) at the waterharvesting flow management location given in Table 1; or
- 30 April.

For the full duration of the first post-winter flow management strategy, the chief executive will apply a 6,000 ML/day (approximately 70 cumec) flow condition for all announced periods for waterharvesting.

#### **10 Assessment of quantity of unsupplemented water taken**

For the assessment of the quantity of unsupplemented water taken under a water allocation:

- A water allocation holder must advise the chief executive prior to taking unsupplemented water;
- A water allocation holder must provide recordings of water taken to the chief executive;
- Only water taken during announced periods may be taken as unsupplemented water;
- The chief executive will advise the Resource Operations Licence holders for the Lower Fitzroy Water Supply Scheme and the Fitzroy Barrage Water Supply Scheme of the meter readings and the approved quantities of unsupplemented water taken within 7 business days of the conclusion of all announced periods for the Fitzroy Water Management Area; and
- Any water taken that is not in accordance with these rules for unsupplemented water and taken from within the limits of the Lower Fitzroy Water Supply Scheme or the Fitzroy Barrage Water Supply Scheme will be treated as supplemented water.

#### **11 Seasonal water assignment rules**

A water allocation holder may apply under Section 142 of the Water Act for a seasonal water assignment for the water year in which the application is made.

An application for a seasonal assignment of a water allocation located in zone Fitzroy A, B, C, D, or E will be approved for:

- All or part of that portion of the volumetric limit for the water allocation that has not been taken in the current water year; if
- The water under seasonal assignment is taken from within zone Fitzroy A, B, C, D or E.

On approval the chief executive will issue a water permit for the seasonal assignment. The conditions for the water permit will include:

- A maximum rate for taking water in the same proportion to the seasonal assignment volume as the maximum rate for taking water is to the volumetric limit stated on the water allocation under seasonal assignment; and
- A passing flow condition the same as the water allocation under seasonal assignment.

On approval of the water permit, the chief executive will reduce the volumetric limit for the current water year and the maximum rate for taking water for the remainder of the current water year for the water allocation under seasonal assignment by the volume and maximum rate specified for the water permit.

The holder of the seasonal assignment water permit must be a holder of a development permit for works used to take the seasonally assigned water.

#### **12 Procedures**

Details of procedures associated with the implementation of these operating rules may be obtained from the chief executive.

# Attachment 5.3F

## Fitzroy Water Management Area

### Operating rules for water allocations with up to 260 ML/day passing flow conditions

These operating rules apply to water allocations with up to 260 ML/day passing flow conditions in the Fitzroy Water Management Area, from the Dawson River junction to the upstream limit of Eden Bann Weir.

#### **1 Water year**

The water year shall be from 1 July to 30 June the following year.

#### **2 Location from which water may be taken**

The location from which water may be taken for a water allocation with a passing flow condition is described on the water allocation as a zone.

The location from which water may be taken for a water allocation without a passing flow condition is specified as two components on a water allocation. The first component is the zone specification. The second component is the position specification, which is the AMTD position along the river within the zone. The holders of these water allocations may take water below the cease to flow level of a waterhole at the AMTD location on the water allocation.

Descriptions of the zones for the Fitzroy River are given in Attachment 2.3.

#### **3 Purpose for which water may be taken**

The purpose for which water may be taken is stated on each water allocation. For the purpose of 'agriculture', water may be taken for agricultural purposes. For the purpose of 'any', water may be taken for any purpose.

#### **4 Maximum volume of water taken**

The maximum volume of water taken in any water year must not exceed the volumetric limit stated on a water allocation.

#### **5 Maximum rate for taking water**

The maximum rate that water may be taken is the maximum rate stated on a water allocation, averaged over any continuous 72-hour period.

Under the provisions of Chapter 8, the chief executive may amend the specified continuous period having regard to water sharing between allocation holders and the objectives of the Water Resource Plan.

## 6 Flow conditions under which water may be taken

The passing flow conditions stated on a water allocation is the stream flow nominally required to pass downstream while water is being taken under the water allocation.

For water allocations with stated passing flow conditions, the chief executive will determine those periods when the passing flow conditions exist and when water may be taken by assessment of stream flows at the flow management location in Table 1. The chief executive will notify water allocation holders when the taking of water is permitted.

For water allocations without stated passing flow conditions the limitations for taking water from waterholes given in Section 7 apply.

**Table 1: Management reaches and flow management locations for water allocations with up to 260 ML/day passing flow conditions**

Management reach	Management reach description	Flow management location
Zones: Fitzroy D, E	Dawson River junction to upstream limit of Eden Bann Weir	Riverslea Gauging Station

## 7 Drawdown conditions for waterholes

The following conditions apply to holders of water allocations without passing flow conditions who may take water below the cease to flow level of a waterhole:

- A water allocation holder must advise the chief executive prior to taking water from a waterhole more than 0.5 metres below the cease to flow level;
- A water allocation holder must keep a daily record of the level of a waterhole below cease to flow level when taking water from a waterhole more than 0.5 metres below the cease to flow level;
- The chief executive may limit the water that may be taken under a water allocation from a waterhole by notifying the holder of a water allocation if the chief executive is satisfied that limitations are necessary for protection of the natural ecosystem, or sharing the available water at times of water shortage. Limits on the water that may be taken may include any one or more of the following:
  - The times when water may be taken by a water allocation holder;
  - The purpose for which water may be taken; and
  - The volume of water that may be taken by a water allocation holder.

## 8 First post-winter flow management strategy

First post-winter flow management strategies do not apply.

## 9 Water allocation holder to record quantity of water taken

Each water allocation holder must record the quantity of water taken and provide the chief executive with those records.

## 10 Seasonal water assignment rules

A water allocation holder may apply under Section 142 of the Water Act for a seasonal water

assignment for the water year in which the application is made.

#### **10.1 Water allocations with 9 and 260 ML/day passing flow conditions**

An application for a seasonal assignment of a water allocation with a 9 or 260 ML/day passing flow condition will be approved for:

- All or part of that portion of the volumetric limit for the water allocation that has not been taken in the current water year; if
- The water under seasonal assignment is taken from within either zone Fitzroy D or E.

On approval the chief executive will issue a water permit for the seasonal assignment. The conditions for the water permit will include:

- A maximum rate for taking water in the same proportion to the seasonal assignment volume as the maximum rate for taking water is to the volumetric limit stated on the water allocation under seasonal assignment; and
- A passing flow condition the same as the water allocation under seasonal assignment.

On approval of the water permit, the chief executive will reduce the volumetric limit for the current water year and the maximum rate for taking water for the remainder of the current water year for the water allocation under seasonal assignment by the volume and maximum rate specified for the water permit.

The holder of the seasonal assignment water permit must be a holder of a development permit for works used to take the seasonally assigned water.

#### **10.2 Water allocations with no passing flow conditions**

An application for a seasonal assignment of a water allocation with no passing flow conditions will be approved for:

- All or part of the portion of the volumetric limit for the water allocation that has not been taken in the current water year; if
- The water under seasonal assignment will be taken from the same waterhole indicated by the AMTD position specified on the water allocation.

On approval the chief executive will issue a water permit for the seasonal assignment. The conditions specified for the water permit will include:

- A maximum rate for taking water in the same proportion to the seasonal assignment volume as the maximum rate for taking water is to the volumetric limit stated on the water allocation under seasonal assignment; and
- No passing flow condition.

On approval of the water permit, the chief executive will reduce the volumetric limit for the current water year and the maximum rate for taking water for the remainder of the current water year for the water allocation under seasonal assignment by the volume and maximum rate specified for the water permit.

The holder of the seasonal assignment water permit must be a holder of a development permit for works used to take the seasonally assigned water.

**11 Procedures**

Details of procedures associated with the implementation of these operating rules can be obtained from the chief executive.

# Attachment 5.3G

## Fitzroy Water Management Area

### Water allocation change rules

#### 1 Permitted changes

Applications for the following changes to a water allocation will be approved. On approval a change certificate will be issued by the chief executive, which may be lodged with the registrar of water allocations.

##### 1.1 Location

###### 1.1.1 Water allocations with 2,592 or 4,320 ML/day passing flow conditions

A change to the location of a water allocation with a 2,592 or 4,320 ML/day passing flow condition from any one of the following zones to any other of those zones:

- Fitzroy A;
- Fitzroy B;
- Fitzroy C;
- Fitzroy D; or
- Fitzroy E.

###### 1.1.2 Water allocations with 9 or 260 ML/day passing flow conditions

A change to the location of a water allocation with a 9 or 260 ML/day passing flow condition from any one of the following zones to any other of those zones:

- Fitzroy D; or
- Fitzroy E.

###### 1.1.3 Water allocations with no flow conditions

A change to the AMTD position specification for the location of a water allocation with no flow conditions to a new AMTD position on the same waterhole that applied to the allocation being changed.

A change to remove the AMTD specification of the location of a water allocation with no flow conditions. A passing flow condition of 9 ML/day will be set for the changed water allocation.

##### 1.2 Purpose

A water allocation holder may apply to change the purpose from 'any' to 'agriculture' or from 'agriculture' to 'any'.

### 1.3 Amalgamation or subdivision

A change to subdivide a water allocation into two or more water allocations, provided:

- The volumes and the maximum rates for each of the new water allocations are in the same proportion as the volumes and the maximum rates for the original water allocation; and
- The sum of the volumes and the maximum rates for the new water allocations is the same as the volumes and the maximum rates for the original allocation.

A change to amalgamate two or more water allocations with the same location and the same flow condition specifications, provided:

- The volumes and the maximum rate for the new water allocation are the combined volumes and the combined maximum rates specified for the original water allocations.

A change to amalgamate two or more water allocations with AMTD position specifications that apply to the same waterhole, provided:

- The volumes and rate for the new water allocation are the combined volumes and the combined rates of the original water allocations; and
- The AMTD specification for the new water allocation applies to the same waterhole as the original water allocations.

## 2 Prohibited changes

The following changes are prohibited changes.

### 2.1 Location

For a water allocation with a 2,592 ML/day or 4,320 ML/day passing flow condition, a change to a location that is not:

- Zone Fitzroy A, B, C, D, or E in the Fitzroy Water Management Area; or
- Zone Mackenzie A, B, C, D, E, F, G, H, I, J, K, or L in the Nogo Mackenzie Water Management Area.

For a water allocation with a 9 ML/day or 260 ML/day passing flow condition or no flow condition, a change to a location that is not:

- Zone Mackenzie A in the Nogo Mackenzie Water Management Area; or
- Zone Fitzroy D or Fitzroy E in the Fitzroy Water Management Area.

### 2.2 Purpose

A change to a purpose that is not 'agriculture' or 'any'.

### 2.3 Volume

A change to the volume of a water allocation that is not a consequence of a change to another attribute of a water allocation.

### 2.4 Rate

A change to the maximum rate of a water allocation that is not a consequence of a change to another attribute of a water allocation.

## **2.5 Supply of water under a resource operations licence**

A change to a water allocation that would result in a water allocation being managed under a Resource Operations Licence.

## **2.6 Other**

A change to a water allocation that requires an amendment to this ROP, other than an amendment provided for in Chapter 8.

## **3 Application for change under Section 130 of the Water Act**

If a water allocation holder wishes to apply for a change to a water allocation that is not permitted under Section 1 above, and not prohibited under Section 2 above, then application may be made under Section 130 of the Water Act for the change.

The chief executive will deal with applications made under Section 130 of the Water Act, in accordance with the Water Act. That process is as follows:

- Notice of the application is published in local newspapers. The notice includes information about where the application can be inspected and invites submissions from the public on the application.
- The chief executive determines if the application should be approved having regard to the potential impact on a range of interests including other entitlement holders and aquatic ecosystems.
- If the chief executive approves the application, the chief executive will issue a change certificate that may be lodged with the registrar of water allocations.
- If the chief executive refuses the application, the Water Act provides for an appeal process.

## **4 Registration of change**

If an application to change a water allocation is approved, the chief executive will issue a change certificate. The water allocation holder may lodge the change certificate with the registrar of water allocations who will change the water allocation on the water allocation register.

# Attachment 5.4

## Seasonal water assignment areas

### 1 Teviot Creek Dam and Burton Gorge Dam

#### 1.1 Area

Seasonal water assignments of water licences are, subject to the rules in Section 1.2, allowed in the following areas:

- The ponded area of Teviot Creek Dam located on Teviot Creek at AMTD 31.0 km; and
- The ponded area of Burton Gorge Dam located on the Isaac River at AMTD 280.7 km.

#### 1.2 Rules for seasonal water assignment

The following rules apply for seasonal water assignment of water licences for the area given in Section 1.1.

A water licence holder may apply under Section 142 of the Water Act for a seasonal water assignment.

Seasonal water assignments are permitted only for water licences that:

- Take water from the ponded area of Teviot Creek Dam and the ponded area of Burton Gorge Dam;
- Specify the amount of water to be taken; and
- Are metered.

The amount of water that may be seasonally assigned under a water licence in a water year may not exceed the unused portion of water for that water licence.

The water year is from 1 July to 30 June the following year.

# Attachment 9.1

## Implementation schedule

The Fitzroy Basin ROP 2003 was approved by the Governor in Council on 18 December 2003 and came into effect on 9 January 2004.

The ROP amendment (Revision 2) takes effect from the date approval of the amendment is notified in the Government Gazette. The ROP amendment (Revision 2) commences on the first business day after the amendment takes effect.

The following specifies requirements for ROP implementation.

### **1 Water supply schemes**

#### **1.1 Dawson Valley Water Supply Scheme**

The operational arrangements for the Dawson Valley Water Supply Scheme commenced on 1 October 2004.

The ROL holder for the Dawson Valley Water Supply Scheme may, where the ROL holder is unable to meet the water quality monitoring requirements under the ROP amendment (Revision 2), continue to operate under the provisions of the ROP 2006 until 30 June 2010.

#### **1.2 Nogoia Mackenzie Water Supply Scheme**

The operational arrangements for the Nogoia Mackenzie Water Supply Scheme commenced on 1 July 2004.

The Fairbairn Dam river outlet must be capable of discharging to the river between 1,500 and 1,600 ML/day when the water level in Fairbairn Dam is at EL 199.0 m AHD within 3 years after the approval of the ROP 2003, unless otherwise authorised by the chief executive. In the interim the ROL holder for the Nogoia Mackenzie Water Supply Scheme may operate the scheme with the Fairbairn Dam river outlet having a discharge capacity of not less than that of the existing outlet works.

The ROL holder for the Nogoia Mackenzie Water Supply Scheme may, where the ROL holder is unable to meet the water quality monitoring requirements under the ROP amendment (Revision 2), continue to operate under the provisions of the ROP 2006 until 30 June 2010.

#### **1.3 Lower Fitzroy Water Supply Scheme**

The operational arrangements for the Lower Fitzroy Water Supply Scheme commenced on 1 July 2004.

The ROL holder for the Lower Fitzroy Water Supply Scheme may, where the ROL holder is unable to meet the water quality monitoring requirements under the ROP amendment

(Revision 2), continue to operate under the provisions of the ROP 2006 until 30 June 2010.

#### **1.4 Fitzroy Barrage Water Supply Scheme**

The operational arrangements for the Fitzroy Barrage Water Supply Scheme commenced on 1 July 2004.

The ROL holder for the Fitzroy Barrage Water Supply Scheme may, where the ROL holder is unable to meet the water quality monitoring requirements under the ROP amendment (Revision 2), continue to operate under the provisions of the ROP 2006 until 30 June 2010.

### **2 Water management areas**

#### **2.1 Dawson Valley Water Management Area**

The operational arrangements for the Dawson Valley Water Management Area commenced on 1 October 2004.

#### **2.2 Nogo Mackenzie Water Management Area**

The operational arrangements for the Nogo Mackenzie Water Management Area commenced on 1 July 2004.

#### **2.3 Fitzroy Water Management Area**

The operational arrangements for the Fitzroy Water Management Area commenced on 1 July 2004.

### **3 Interim arrangements**

The chief executive may approve interim administrative arrangements for the implementation of matters not specifically referred to in this implementation schedule.

## Attachment 9.2 Amendment history

---

The Fitzroy Basin ROP 2003 was approved by the Governor in Council on 18 December 2003 and came into effect on 9 January 2004.

The ROP has been amended as follows:

Revision 1 (April 2006) under section 106 of the *Water Act 2000*

Revision 2 (July 2009) under sections 105 and 106 of the *Water Act 2000*

Queensland

# Water Resource (Fitzroy Basin) Plan 2010

Subordinate Legislation 2010 No. ...

made under the

*Water Act 2000*

## Chapter 1 Preliminary

### 1 Short title

This plan may be cited as the *Water Resource (Fitzroy Basin) Plan 2010*.

### 2 Purposes of plan

The following are the purposes of this plan—

- (a) to define the availability of water in the plan area;
- (b) to provide a framework for sustainably managing water and the taking of water;
- (c) to identify priorities and mechanisms for dealing with future water requirements;
- (d) to provide a framework for establishing water allocations;
- (e) to provide a framework for minimising, where practicable, degradation in natural ecosystems;
- (f) to regulate the taking of overland flow water;
- (g) to regulate the taking of groundwater.

### 3 Definitions

The dictionary in schedule 13 defines particular words used in this plan.

[s 4]

---

## Chapter 2 Plan area and water to which plan applies

### 4 Plan area

This plan applies to the area shown as the plan area on the map in schedule 1.

### 5 Subcatchment areas

Each part of the plan area that is within a subcatchment area shown on the map in schedule 2 is a subcatchment area for this plan.

### 6 Groundwater management areas

Each part of the plan area that is within a groundwater management area shown on the map in schedule 3 is a groundwater management area for this plan.

### 7 Groundwater units and groundwater sub-areas

- (1) The Callide groundwater management area consists of the following (each a *groundwater unit*)—
  - (a) Callide Groundwater Unit 1, containing the aquifers of the quaternary alluvium;
  - (b) Callide Groundwater Unit 2, containing all subartesian aquifers within the Callide groundwater management area other than the aquifers included in Callide Groundwater Unit 1.
- (2) Each of the following areas of the Callide Groundwater Unit 1 shown on maps A to D in schedule 4 is a groundwater sub-area for this plan—
  - (a) Upper Callide groundwater sub-area;
  - (b) Lower Callide groundwater sub-area;

- 
- (c) Prospect Creek groundwater sub-area;
  - (d) Don and Dee groundwater sub-area.
- (3) The Isaac Connors groundwater management area consists of the following (also each a ***groundwater unit***)—
- (a) Isaac Connors Groundwater Unit 1, containing the aquifers of the quaternary alluvium;
  - (b) Isaac Connors Groundwater Unit 2, containing all subartesian aquifers within the Isaac Connors groundwater management area other than the aquifers included in Isaac Connors Groundwater Unit 1.
- (4) The area of Isaac Connors Groundwater Unit 1 shown on map E in schedule 4 is the Isaac Connors Alluvium groundwater sub-area for this plan.
- (5) The Highlands groundwater management area consists of the following (also each a ***groundwater unit***)—
- (a) Highlands Groundwater Unit 1, containing the aquifers of the quaternary alluvium;
  - (b) Highlands Groundwater Unit 2, containing all subartesian aquifers within the Highlands groundwater management area other than the aquifers included in Highlands Groundwater Unit 1.
- (6) The area of Highlands Groundwater Unit 1 shown on map F in schedule 4 is the Sandy Creek Alluvium groundwater sub-area for this plan.
- (7) The Fitzroy groundwater management area consists of the following (also each a ***groundwater unit***)—
- (a) Fitzroy Groundwater Unit 1, containing the aquifers of the modern coastal deposits;
  - (b) Fitzroy Groundwater Unit 2, containing all subartesian aquifers within the Fitzroy groundwater management area other than the aquifers included in Fitzroy Groundwater Unit 1.

[s 8]

---

**8 Information about areas**

- (1) The exact location of the boundaries of the plan area, subcatchment areas, groundwater management areas and groundwater sub-areas is held in digital electronic form by the department.
- (2) The information held in digital electronic form can be reduced or enlarged to show the details of the boundaries.

**9 Nodes**

- (1) A node mentioned in this plan is a place—
  - (a) on a watercourse in the plan area; or
  - (b) in a groundwater management area in the plan area.
- (2) The location of each node is—
  - (a) shown on the map in schedule 5, part 1 or schedule 5, part 2; and
  - (b) described in schedule 5, part 3 or schedule 5, part 4.
- (3) Each node is identified on the map by a number.

**10 Water to which plan applies**

- (1) This plan applies to the following water (*surface water*) in the plan area—
  - (a) water in a watercourse or lake;
  - (b) water in a spring not connected to—
    - (i) artesian water; or
    - (ii) subartesian water connected to artesian water;
  - (c) overland flow water other than water in a spring connected to—
    - (i) artesian water; or
    - (ii) subartesian water connected to artesian water.
- (2) This plan also applies to groundwater in the plan area.

## Chapter 3 Outcomes for sustainable management of water

### 11 Outcomes for water in plan area

Water is to be allocated and sustainably managed in a way that—

- (a) recognises the natural state of watercourses, lakes, springs and aquifers has changed because of the taking of, and interfering with, water; and
- (b) seeks to achieve a balance in the following outcomes—
  - (i) the general outcomes mentioned in section 12;
  - (ii) the specific surface water and groundwater outcomes mentioned in section 13;
  - (iii) the general ecological outcomes mentioned in section 14;
  - (iv) the specific ecological outcomes mentioned in section 15.

### 12 General outcomes

Each of the following is a general outcome for water in the plan area—

- (a) to provide for the use of water entitlements and other authorisations in the plan area;
- (b) to provide for the continued use of existing overland flow works;
- (c) to provide for the continued use of existing groundwater works;
- (d) to protect the probability of being able to take water under a water allocation;
- (e) to support water-related cultural values including the values of the traditional owners in the plan area;

[s 13]

---

- (f) to provide mechanisms that support water being made available for the following—
  - (i) population growth in towns and communities dependent on water resources in the plan area;
  - (ii) growth in industries dependent on water resources in the plan area;
  - (iii) stock or domestic purposes in the plan area;
  - (iv) Indigenous communities dependent on water resources in the plan area to achieve their economic and social aspirations;
- (g) to support flexible and diverse water supply arrangements for consumptive water users;
- (h) to maintain flows that support water-related aesthetic, economic and recreational values in the plan area, including, for example, tourism;
- (i) to encourage continual improvement in the efficient use of water;
- (j) to provide a flow regime that supports the quality of water for human and ecological use.

**13 Specific surface water and groundwater outcomes**

- (1) Each of the following is a specific outcome for surface water in the plan area—
  - (a) to make water available in the Isaac Connors subcatchment to support—
    - (i) water supplies for mining; and
    - (ii) growth in the population of towns and communities, industry and agriculture;
  - (b) to make water available in the Upper Dawson and Lower Dawson subcatchments to support—
    - (i) water supplies for mining and industry; and

- 
- (ii) growth in the population of towns and communities and agriculture;
  - (c) to make water available in the Fitzroy subcatchment to support urban, industrial and other uses.
- (2) Each of the following is a specific outcome for groundwater in the Upper Callide, Lower Callide and Prospect Creek groundwater sub-areas and the Callide Valley Water Supply Scheme—
- (a) to provide for the use of groundwater that can be sustained in the long term;
  - (b) to provide for increased security for town water supplies and rural water supply boards that rely on groundwater;
  - (c) to provide security of supply for existing enterprises that rely on groundwater.

#### **14 General ecological outcomes**

Each of the following is a general ecological outcome for water in the plan area—

- (a) to minimise changes to the natural variability of flows that support aquatic ecosystems;
- (b) to provide for the continued capability of 1 part of the river system to be connected to another, including by maintaining flows that—
  - (i) allow for the movement of native aquatic fauna between riverine, floodplain, wetland, estuarine and marine environments; and
  - (ii) support water-related ecosystems; and
  - (iii) support river-forming processes;
- (c) to provide a flow regime that—
  - (i) maintains delivery of fresh water to the estuaries of watercourses and the Great Barrier Reef Lagoon; and

[s 15]

---

- (ii) supports productivity in the receiving waters of the Great Barrier Reef and inshore reefs;
- (d) to improve understanding of the matters affecting the flow-related health of ecosystems in the plan area;
- (e) to minimise the impact of the taking of water on aquatic ecosystems, including ecological assets;
- (f) to protect and maintain refugia associated with waterholes, lakes and wetlands;
- (g) to support surface water and groundwater interactions;
- (h) to support ecosystems dependent on groundwater including, for example, riparian vegetation and wetlands.

**15 Specific ecological outcomes**

Each of the following is a specific ecological outcome for water in the plan area—

- (a) to protect flows and water quality for flow-spawning fish and endemic species, including, for example, the Fitzroy golden perch (*Macquaria ambigua orientis*);
- (b) to provide for flows necessary for estuarine ecosystem functions, including flows for—
  - (i) barramundi (*Lates calcarifer*) and king threadfin salmon (*Polydactylus macrochir*) recruitment; and
  - (ii) banana prawn (*Penaeus merguensis*) growth;
- (c) to provide for groundwater levels to support relevant groundwater-dependent ecosystems and wetlands that rely on groundwater in—
  - (i) the Upper Callide groundwater sub-area; and
  - (ii) the Lower Callide groundwater sub-area; and
  - (iii) the Prospect Creek groundwater sub-area; and
  - (iv) the Callide Valley Water Supply Scheme;

- 
- (d) to maintain groundwater discharge to watercourses in the Isaac Connors groundwater management area.

## **Chapter 4 Performance indicators and objectives**

### **Part 1 Environmental flow objectives**

#### **Division 1 Surface water**

##### **16 Performance indicators for environmental flow objectives**

The performance indicators for the environmental flow objectives are—

- (a) for assessing periods of low flow—the base flow; and
- (b) for assessing periods of medium to high flow, the following—
  - (i) mean annual flow;
  - (ii) median annual flow ratio;
  - (iii) annual proportional flow deviation;
  - (iv) mean wet season flow;
  - (v) 4% daily exceedance duration flow;
  - (vi) 10% daily exceedance duration flow;
  - (vii) 2 year daily flow volume;
  - (viii) 5 year daily flow volume;
  - (ix) 20 year daily flow volume; and

[s 17]

---

- (c) for assessing the first post-winter flow event—the performance indicators listed in schedule 6, part 3.

**17 Environmental flow objectives**

The environmental flow objectives for surface water for this plan are stated in schedule 6, parts 1 to 3.

**Division 2 Groundwater**

**18 Performance indicators for environmental flow objectives—relevant groundwater-dependent ecosystems**

The performance indicator for the environmental flow objectives for assessing groundwater levels to support relevant groundwater-dependent ecosystems is the drawdown duration.

**19 Environmental flow objectives**

The environmental flow objectives for groundwater for this plan are stated in schedule 6, part 4.

**Part 2 Water allocation security objectives**

**20 Performance indicators for water allocation security objectives**

The performance indicators for the water allocation security objectives are—

- (a) for taking supplemented surface water, the following—
  - (i) annual supplemented water sharing index;

- (ii) monthly supplemented water sharing index; and
- (b) for taking unsupplemented surface water—the annual volume probability; and
- (c) for taking supplemented groundwater—the annual supplemented water sharing index; and
- (d) for taking unsupplemented groundwater—the annual volume probability.

**21 Water allocation security objectives**

The water allocation security objectives for this plan are stated in—

- (a) for water allocations to take supplemented water—schedule 7, part 1; and
- (b) for water allocations to take unsupplemented surface water—schedule 7, part 2; and
- (c) for water allocations to take unsupplemented groundwater—schedule 7, part 3.

**Chapter 5 Strategies for achieving outcomes**

**Part 1 Strategies for both surface water and groundwater**

**Division 1 General provisions**

**22 Application of pt 1**

This part applies to surface water and groundwater.

[s 23]

---

**23 Decisions to be consistent with objectives**

Decisions about the allocation or management of water in the plan area, other than a decision about a water permit, must be consistent with—

- (a) the environmental flow objectives stated in schedule 6; and
- (b) the water allocation security objectives stated in schedule 7.

**24 Assessing impact of decisions about surface water**

- (1) The IQQM computer program’s simulation for the simulation period is used to assess consistency with the environmental flow objectives and the water allocation security objectives for surface water.
- (2) If it is not practicable to use the IQQM computer program, another assessment method approved by the chief executive may be used.
- (3) The chief executive may approve an assessment method for subsection (2) only if the chief executive is satisfied the method will assess consistency with the objectives at least as accurately as the IQQM computer program.

**25 Assessing impact of decisions about groundwater**

- (1) The Callide Valley groundwater computer program’s simulation for the simulation period is used to assess consistency with the environmental flow objectives and the water allocation security objectives for groundwater.
- (2) If it is not practicable to use the Callide Valley groundwater computer program, another assessment method approved by the chief executive may be used.
- (3) The chief executive may approve an assessment method for subsection (2) only if the chief executive is satisfied the method will assess consistency with the objectives at least as

---

accurately as the Callide Valley groundwater computer program.

## 26 Measuring devices

A measuring device is to be used to measure the volume of water taken under the following water entitlements in the plan area—

- (a) an interim water allocation;
- (b) a water allocation;
- (c) a water licence for taking water.

*Note—*

For the compulsory use of meters for taking water in the State, see the *Water Regulation 2002*, part 7.

## 27 Matters to be considered for environmental management rules

- (1) In deciding the environmental management rules to be included in the resource operations plan, the chief executive is to consider—
  - (a) the streamflows required to maintain the following—
    - (i) the longitudinal connectivity of low flow habitats throughout river systems in the plan area;
    - (ii) the wetted habitats at riffles and other streambed features;
    - (iii) the natural seasonality of flows;
    - (iv) the replenishment of refuge pools that enable movement of instream biota;
    - (v) the lateral connectivity between rivers in the plan area and their adjacent riverine environments including floodplains;

[s 27]

---

- (vi) the connectivity, through the flow of water, between a watercourse, lake or spring and groundwater to replenish aquifers;
- (vii) the first post-winter flow event at nodes downstream of supplemented water infrastructure; and
- (b) the distance of a water bore from a watercourse, lake, spring or area of ecological value; and
- (c) the groundwater levels required to maintain the following—
  - (i) habitats needed by aquatic biota in hyporheic zones;
  - (ii) relevant groundwater-dependent ecosystems;
  - (iii) the connectivity through the flow of water between an aquifer and an adjacent watercourse, lake or spring to replenish instream pools and enable movement of instream aquatic biota;
  - (iv) the natural seasonality of low flows; and
- (d) the impact the taking of, or interfering with, water may have on the following—
  - (i) instream water levels;
  - (ii) water quality;
  - (iii) baseflow;
  - (iv) groundwater levels;
  - (v) the natural movement of sediment;
  - (vi) the bed and banks of a watercourse or lake;
  - (vii) riparian vegetation;
  - (viii) habitats for native plants and animals;
  - (ix) the contribution from aquifers to the flow of water in watercourses;
  - (x) the inundation of habitats;

- (xi) the movement of fish and other aquatic animals;
  - (xii) the ecological values of waterholes, lakes, springs, relevant groundwater-dependent ecosystems or hyporheic zones;
  - (xiii) the recreation and aesthetic values of the plan area;
  - (xiv) cultural values including, for example, cultural values of traditional owners of an area.
- (2) Subsection (1) does not limit the matters the chief executive may consider.

**28 Matters to be considered for water sharing rules**

- (1) In deciding the water sharing rules to be included in the resource operations plan, for authorisations to take water in a part of the plan area, the chief executive is to consider—
- (a) for rules relating to supplemented surface water, the following—
    - (i) any existing water sharing arrangements;
    - (ii) the extent to which any existing water supply arrangements are linked to the natural occurrence of streamflows;
    - (iii) the frequency, duration, magnitude and timing of limited water availability;
    - (iv) the impact of the rules on authorisations to take water in the plan area;
    - (v) the impact of the rules on unsupplemented water allocations, particularly as assessed under—
      - (A) the 30% unsupplemented water sharing index; and
      - (B) the 50% unsupplemented water sharing index; and
      - (C) the 70% unsupplemented water sharing index; and

[s 28]

---

- (b) for rules relating to unsupplemented surface water, the following—
  - (i) any existing water sharing arrangements;
  - (ii) the local availability of water that may be taken from streamflows, waterholes or bedsands;
  - (iii) the conditions for taking water;
  - (iv) the volumetric limits for the water entitlements;
  - (v) the impact of the rules on authorisations to take water in the plan area;
  - (vi) the impact of the rules on unsupplemented water allocations, particularly as assessed under—
    - (A) the 30% unsupplemented water sharing index; and
    - (B) the 50% unsupplemented water sharing index; and
    - (C) the 70% unsupplemented water sharing index; and
- (c) for rules relating to groundwater in the Upper Callide, Lower Callide and Prospect Creek groundwater sub-areas and the Callide Valley Water Supply Scheme—
  - (i) the matters mentioned in paragraph (e); and
  - (ii) the range of historical water levels in the groundwater sub-areas and Callide Valley Water Supply Scheme from 1970 to 2007; and
- (d) for rules relating to groundwater in Isaac Connors Groundwater Unit 1—
  - (i) the matters mentioned in paragraph (e); and
  - (ii) the range of historical water levels and extraction in the Braeside Borefield; and
- (e) for rules relating to other groundwater, the following—

- (i) any existing water sharing arrangements;
  - (ii) the local availability of water that may be taken from aquifers;
  - (iii) the connectivity of surface water and groundwater;
  - (iv) the impact of the taking of groundwater on authorisations in the groundwater management areas;
  - (v) the operating arrangements and supply requirements for any water infrastructure;
  - (vi) the volumetric limits for water entitlements.
- (2) Subsection (1) does not limit the matters the chief executive may consider.
- (3) In this section—
- existing water sharing arrangements* means water sharing rules specified in the following on the day this plan is notified—
- (a) the Fitzroy Basin Resource Operations Plan 2004;
  - (b) the *Water Regulation 2002*;
  - (c) the Callide Valley Water Supply Scheme interim resource operations licence (IROL);
  - (d) the Department of Environment and Resource Management's policy no. WMU/2005/2209 for the Callide Valley groundwater management area.

**29 Matters to be considered for water allocation change rules**

- (1) In deciding the water allocation change rules to be included in the resource operations plan for authorisations to take surface water in a part of the plan area, the chief executive is to consider—

[s 29]

---

- (a) the implications for the availability of water under water allocations of changes to the frequency, duration, magnitude and timing of limited water availability; and
  - (b) the impact of the rules on unsupplemented water allocations, particularly as assessed under—
    - (i) the 30% unsupplemented water sharing index; and
    - (ii) the 50% unsupplemented water sharing index; and
    - (iii) the 70% unsupplemented water sharing index.
- (2) In deciding the water allocation change rules to be included in the resource operations plan for authorisations to take groundwater, the chief executive is to consider—
- (a) the volume density for a locality in part of the groundwater management area relative to the availability of water in that part; and
  - (b) the impact the proposed taking of groundwater would have on the following—
    - (i) watercourses, lakes, springs, baseflows, waterholes, groundwater levels or areas of ecological value;
    - (ii) the ecological values of relevant groundwater-dependent ecosystems;
    - (iii) water quality;
    - (iv) other authorisations in the area of the proposed taking; and
  - (c) existing management zones; and
  - (d) for water allocations to take water in the Callide Valley Water Supply Scheme—the ability of an allocation holder to change the priority group of water allocations from medium to high B.
- (3) Subsections (1) and (2) do not limit the matters the chief executive may consider.

**30 Matters to be considered for infrastructure operating rules**

- (1) In deciding the infrastructure operating rules to be included in the resource operations plan for water infrastructure or proposed infrastructure for supplemented water, the chief executive is to consider the following—
  - (a) the impact of the infrastructure's or proposed infrastructure's operation on the following—
    - (i) water quality;
    - (ii) instream water levels;
    - (iii) groundwater levels;
    - (iv) beds and banks of watercourses;
    - (v) riparian vegetation;
  - (b) the extent to which artificial variations in instream water levels and flows may adversely affect natural ecosystems;
  - (c) the impact of the transfer of water between watercourses;
  - (d) the likelihood of aquatic fauna deaths caused by the operation of the infrastructure;
  - (e) the matters mentioned in section 27(1)(a) and (d).
- (2) Subsection (1) does not limit the matters the chief executive may consider.

[s 31]

---

## **Division 2                      Continued effect of moratorium and interim arrangements for applications**

### **31                      Continued effect of moratorium notice published on 13 September 2001—Act, s 46(3)**

- (1) This section amends and continues, in part, the effect of the moratorium notice published on 13 September 2001 and amended on 29 October 2001, 10 December 2003 and 17 May 2004 and continued under the previous water resource plan.
- (2) Until an amendment to the resource operations plan, in relation to overland flow water, is approved—
  - (a) new works must not be physically started; and
  - (b) completed, or partly completed, works in existence must not be raised, enlarged or deepened.
- (3) Subsection (2) applies only to works for taking or storing water from a watercourse, lake or spring that may increase the taking of overland flow water, if the works are for taking or storing water from the following watercourses—
  - (a) Theresa Creek from its junction with Retreat Creek at AMTD 15.0km to its junction with the Nogoia River;
  - (b) Retreat Creek, including anabranes, from its junction with Kettle Creek at AMTD 23.6km to its junction with Theresa Creek;
  - (c) Comet River, including anabranes, from Lake Brown gauging station AMTD 199.2km to its junction with the Nogoia River.
- (4) This section does not apply to works for taking—
  - (a) water under an authorisation that states an area that may be irrigated; or
  - (b) only supplemented water; or
  - (c) water under a water permit; or

- (d) water under section 20(2), (3), (4) or (5) of the Act.
- (5) However, this section applies to works for storing water taken under an authorisation mentioned in subsection (4)(a).
- (6) In this section—  
*previous water resource plan* means the repealed *Water Resource (Fitzroy Basin) Plan 1999*.

**32 Continued effect of moratorium notice published in December 2010—Act, s 46(3)**

- (1) This section continues, in part, the effect of the moratorium notice published in December 2010.
- (2) This section applies to—
  - (a) groundwater in a groundwater management area; and
  - (b) water in a watercourse, lake or spring in the Downstream of Fitzroy Barrage subcatchment area.
- (3) Until an amendment to the resource operations plan to deal with the water mentioned in subsection (2) is approved, an application made under the Act for or about a water licence will not be accepted if granting the application would increase the amount of water that may be taken from the water mentioned in subsection (2).
- (4) This section does not apply to an application—
  - (a) mentioned in section 36; or
  - (b) to take groundwater, other than from Callide Groundwater Unit 1, for mine dewatering purposes; or
  - (c) to reinstate, under section 221 of the Act, an expired water licence; or
  - (d) to replace, under section 229 of the Act, an expired licence with 1 or more licences.

[s 33]

---

**33 Particular applications made before commencement of plan**

- (1) This section applies to an application made under the Act, or repealed Act, before the 2010 moratorium publication day and not finally decided before the commencement of this plan—
  - (a) for a water licence to take groundwater from a groundwater management area; or
  - (b) for a water licence to take water from a watercourse, lake or spring in the Downstream of Fitzroy Barrage subcatchment area shown on the map in schedule 2; or
  - (c) for a water licence to interfere with the flow of water by impounding water in the plan area.
- (2) The application must be refused if granting the application would have 1 or more of the following effects on water to which this plan applies—
  - (a) increase the amount of water that may be taken;
  - (b) increase or change the interference with the water.
- (3) This section does not apply to an application to—
  - (a) take groundwater for stock or domestic purposes; or
  - (b) take groundwater from an area other than Callide Groundwater Unit 1—
    - (i) for mine dewatering purposes; or
    - (ii) for town water supply purposes; or
    - (iii) for a project declared under the *State Development and Public Works Organisation Act 1971*, section 26 to be a significant project; or
    - (iv) for the construction, operation or maintenance of public utilities; or
    - (v) if there is a current development permit authorising construction of works to take the water to which the application relates; or

- (c) take water from a watercourse, lake or spring in the Downstream of Fitzroy Barrage subcatchment area—
  - (i) for town water supply purposes; or
  - (ii) for stock or domestic purposes; or
  - (iii) for a project declared under the *State Development and Public Works Organisation Act 1971*, section 26 to be a significant project; or
- (d) interfere with water by impoundment—
  - (i) for town water supply purposes; or
  - (ii) for stock or domestic purposes; or
  - (iii) for a project declared under the *State Development and Public Works Organisation Act 1971*, section 26 to be a significant project; or
  - (iv) to meet the requirements of an environmental authority issued under the *Environmental Protection Act 1994*; or
- (e) reinstate, under section 221 of the Act, an expired water licence; or
- (f) replace, under section 229 of the Act, an expired licence with 1 or more licences.

**34 Particular provisions of the resource operations plan cease to have effect—Act, s 106A**

On the commencement of this water resource plan, chapter 6, sections 6.1 to 6.7 of the Fitzroy Basin Resource Operations Plan 2004 cease to have effect for the plan area to which this plan applies.

**35 Interim arrangements for particular applications**

- (1) This section applies—
  - (a) to an application for a water licence, made under section 206 of the Act, to take water from a watercourse, lake or

[s 36]

---

spring in the plan area other than in the Downstream of the Fitzroy Barrage subcatchment area; and

- (b) until an amendment to the resource operations plan is approved to state a new process for deciding the applications mentioned in paragraph (a).
- (2) The application must be refused if granting the application would increase the amount of water that may be taken.
- (3) This section does not apply to an application—
  - (a) mentioned in section 36; or
  - (b) to reinstate, under section 221 of the Act, an expired water licence; or
  - (c) to replace, under section 229 of the Act, an expired licence with 1 or more licences.

**36 Interim arrangements for applications about unallocated water—Act, s 106A(3)**

- (1) This section applies until an amendment to the resource operations plan is approved to state a new process for deciding an application relating to the use of unallocated water for—
  - (a) a State purpose; or
  - (b) stock or domestic purposes; or
  - (c) an Indigenous purpose.
- (2) Any volume of water allocated to a successful application mentioned in subsection (1) must be granted from—
  - (a) for water to be used for a State purpose—the strategic reserve, strategic water infrastructure reserve or general reserve; or
  - (b) for water to be used for stock or domestic purposes—the general reserve; or
  - (c) for water to be used for an Indigenous purpose—the strategic reserve.

---

**Division 3                      Unallocated water reserves**

**Subdivision 1                Preliminary**

**37            Application of div 3**

This division applies to unallocated water.

**Subdivision 2                Strategic reserve, strategic water  
infrastructure reserve and general  
reserve**

**38            Unallocated water held as strategic reserve, strategic  
water infrastructure reserve and general reserve**

Unallocated water in the plan area is divided into a strategic reserve, strategic water infrastructure reserve and general reserve.

**Subdivision 3                Unallocated water held as strategic  
reserve**

**39            Purpose for which unallocated water held as strategic  
reserve may be granted**

Unallocated water held as a strategic reserve may be granted only if the water is to be taken for a State purpose or an Indigenous purpose.

**40            Reserve volumes**

- (1) The total of the nominal entitlements for all water licences to take unallocated surface water for a State purpose granted from the strategic reserve in a subcatchment area mentioned

[s 41]

---

in schedule 8, part 1, column 1 is stated in schedule 8, part 1, column 2 opposite the area.

- (2) The total of the nominal entitlements for all water licences to take unallocated surface water for an Indigenous purpose granted from the strategic reserve in a subcatchment area mentioned in schedule 8, part 1, column 1 is stated in schedule 8, part 1, column 3 opposite the area.
- (3) The total of the nominal entitlements for all water licences to take unallocated groundwater from the strategic reserve in a groundwater management area, groundwater unit or groundwater sub-area mentioned in schedule 8, part 2, column 1 is stated in schedule 8, part 2, column 2 opposite the area.

**41 Period for which water is granted for particular State purpose**

- (1) This section applies to the volume of water granted from the strategic reserve for either of the following State purposes—
  - (a) a project of State significance;
  - (b) a project of regional significance.
- (2) The volume of water is granted only for the life of the project and on conclusion of the project the volume of water returns to the strategic reserve.

**42 Projects that may be considered to be of regional significance**

The chief executive may consider a particular project to be a project of regional significance for the plan area only if the chief executive considers the project is significant for a region in the plan area having regard to the following—

- (a) the outcomes stated in chapter 3;
- (b) the economic or social impact the project will have on the region;

- (c) the public interest and the welfare of people in the region;
- (d) any other relevant consideration.

**43 Period for which water is granted for particular Indigenous purpose**

- (1) This section applies to the volume of water granted from the strategic reserve for an Indigenous purpose.
- (2) The volume of water is granted only for the life of the project and on conclusion of the project the volume of water returns to the strategic reserve.

**Subdivision 4 Unallocated water held as strategic water infrastructure reserve**

**44 Purpose for which unallocated water held as strategic water infrastructure reserve may be granted**

Unallocated water held as a strategic water infrastructure reserve may only be granted for water infrastructure mentioned in section 45.

**45 Reserve volumes**

The total of the nominal volumes for all supplemented water allocations to take unallocated water granted from the strategic water infrastructure reserve is the following—

- (a) for water infrastructure on the Dawson River—90000ML;
- (b) for water infrastructure on the Connors River—56400ML;
- (c) for water infrastructure on the Fitzroy River—76000ML.

[s 46]

---

## **Subdivision 5      Unallocated water held as general reserve**

### **46      Purpose for which unallocated water held as general reserve may be granted**

Unallocated water held as a general reserve may be granted for any purpose.

### **47      Reserve volumes**

- (1) The total of the mean annual diversions for all water licences or water allocations to take unallocated surface water granted from the general reserve in a subcatchment area mentioned in schedule 8, part 3, column 1 is stated in schedule 8, part 3, column 2 opposite the area.
- (2) The total of the nominal volume for all water allocations to take unallocated surface water granted from the general reserve in a subcatchment area mentioned in schedule 8, part 4, column 1 is stated in schedule 8, part 4, column 2 opposite the area.
- (3) The total of the nominal entitlement for all water licences to take unallocated groundwater from the general reserve in a groundwater management area, groundwater unit or groundwater sub-area mentioned in schedule 8, part 5, column 1 is stated in schedule 8, part 5, column 2 opposite the area.

## **Subdivision 6      Dealing with unallocated water under the resource operations plan**

### **48      Process for dealing with unallocated water**

- (1) The resource operations plan is to be amended to include the process for dealing with unallocated water specified in this plan.

- 
- (2) In preparing and implementing the process, the chief executive is to consider the following—
- (a) the purpose for which the water is required;
  - (b) the efficiency of existing and proposed water use practices;
  - (c) the extent to which water is being taken under existing authorisations in the plan area;
  - (d) the availability of an alternative water supply for the purpose for which the water is required;
  - (e) the impact the proposed taking of, or interfering with, the water may have on existing water users and the operations of resource operations licence holders and interim resource operations licence holders in the plan area;
  - (f) the matters mentioned in section 27(1)(a) to (d);
  - (g) for the taking of groundwater, the availability of water within a given aquifer.
- (3) Subsection (2) does not limit the matters the chief executive may consider.

## **Division 4                      Callide Valley Water Supply Scheme**

### **Subdivision 1                Resource operations licence**

#### **49            Water allocations to be managed under a resource operations licence**

Water allocations converted from interim water allocations to take supplemented water from the Callide Valley Water Supply Scheme are managed under a resource operations licence.

[s 50]

---

## **Subdivision 2      Converting authorisations to water allocations to take supplemented water**

### **50      Purpose of sdiv 2**

This subdivision states strategies for interim water allocations for the Callide Valley Water Supply Scheme to be converted, under section 121 of the Act, to water allocations to take supplemented water under the resource operations plan.

### **51      Converting interim water allocations to take water from Callide Valley Water Supply Scheme**

Interim water allocations to take water from the Callide Valley Water Supply Scheme are to be converted under the resource operations plan to a water allocation to take supplemented water.

### **52      Elements of water allocations**

A water allocation to take supplemented water is to state the following—

- (a) the location from which water may be taken under the allocation;
- (b) the purpose for which water may be taken under the allocation;
- (c) the nominal volume for the allocation;
- (d) the priority group to which the allocation belongs;
- (e) the conditions, if any, that apply for the allocation.

### **53      Location for taking water under a water allocation**

The location for taking water to be stated on a water allocation to take supplemented water is to include the place at which

---

water could have been taken under the authorisation from which the allocation was converted.

**54 Purpose to be stated on a water allocation**

The purpose to be stated on a water allocation to take supplemented water is to be—

- (a) if the purpose stated on the authorisation is stock, domestic, irrigation, stock intensive, agriculture or a similar purpose—‘agriculture’; or
- (b) otherwise—‘any’.

**55 Nominal volume for a water allocation**

The nominal volume for a water allocation to take supplemented water is to be—

- (a) for water allocations converted from interim water allocations that belong to the risk or high priority groups—the volume stated on the interim water allocation; or
- (b) for all other water allocations converted from interim water allocations—the volume calculated under section 139.

**56 Priority groups for water allocations**

- (1) In the Callide Valley Water Supply Scheme, a water allocation to take supplemented water belongs to—
  - (a) for an authorisation identified by an interim resource operations licence as high priority—the high A priority group; or
  - (b) for an authorisation identified by an interim resource operations licence as medium priority—the medium priority group; or

[s 57]

---

- (c) for an authorisation identified by an interim resource operations licence as risk priority—the risk priority group.
- (2) However, water allocations converted from interim water allocations 35687D and 47297D belong to the high B priority group.

**57 Conditions for water allocations**

In deciding the conditions under which water may be taken under a water allocation to take supplemented water, the chief executive must consider any conditions stated on the authorisation from which the allocation was converted.

**Part 2 Additional strategies for surface water**

**Division 1 Preliminary**

**58 Application of pt 2**

The strategies stated in this part apply to surface water in addition to the strategies stated in part 1.

**59 Restrictions on taking water from waterholes or lakes**

- (1) This section applies to the chief executive in making a decision about—
  - (a) a water licence to take unsupplemented water; or
  - (b) converting an authorisation to take unsupplemented water into a water allocation; or

- 
- (c) the management of water under a resource operations licence, a distribution operations licence or an interim resource operations licence.
  - (2) If the water licence, water allocation, resource operations licence, distribution operations licence or interim resource operations licence allows the taking of water from a waterhole or lake, the chief executive must—
    - (a) consider the impact the taking may have on the cultural or ecological values of the waterhole or lake; and
    - (b) impose a condition on the water licence, water allocation, resource operations licence, distribution operations licence or interim resource operations licence about maintaining the cultural or ecological values of the waterhole or lake.

*Example for paragraph (b)—*

a condition that the water may be taken only if the water level in the waterhole or lake is above the level that is 0.5m below the level at which it naturally overflows

- (3) However, the chief executive need not impose a condition mentioned in subsection (2)(b) if the chief executive is satisfied—
  - (a) the taking of water from the waterhole or lake will not adversely affect its cultural or ecological values; or
  - (b) for a water licence or water allocation that replaces an authorisation in force immediately before the commencement of this plan—the holder of the authorisation would suffer economic hardship if the condition were imposed.

[s 60]

---

**Division 2                      Dawson Valley Water Supply Scheme**

**60            Water allocation to be managed under a resource operations licence**

The water allocation converted from interim water allocation 102930 to take water from the Dawson Valley Water Supply Scheme is managed under a resource operations licence.

**61            Conversion of interim water allocation 102930**

A water allocation converted, under the resource operations plan, from interim water allocation 102930 is to state the following—

- (a) a location decided by considering the authorised activity stated on interim water allocation 102930;
- (b) a purpose of agriculture;
- (c) a nominal volume of 105ML;
- (d) a priority group of medium.

**Division 3                      Process for granting and amending interim resource operations licences**

**Subdivision 1            Preliminary**

**62            Application and purpose of div 3**

This division—

- (a) states a process for granting an interim resource operations licence to meet future water requirements under section 176 of the Act; and

- (b) states a process for amending an interim resource operations licence to meet future water requirements under section 184A of the Act; and
- (c) applies only to the granting or amendment of an interim resource operations licence for a project declared under the *State Development and Public Works Organisation Act 1971*, section 26 to be a significant project; and
- (d) applies until an amendment to the resource operations plan is approved to state a process mentioned in paragraphs (a) and (b).

## **Subdivision 2 Interim resource operations licence for particular infrastructure**

### **63 Applying for, or to amend, interim resource operations licence**

- (1) This section applies to the proposed owner of infrastructure for a project declared under the *State Development and Public Works Organisation Act 1971*, section 26 to be a significant project.
- (2) The chief executive may give notice to the proposed owner that the proposed owner must apply for—
  - (a) an interim resource operations licence to operate the infrastructure; or
  - (b) an amendment of an interim resource operations licence, already held by the proposed owner, to operate the infrastructure.
- (3) If the chief executive gives the proposed owner notice under subsection (2)—
  - (a) the proposed owner must apply in the approved form; and
  - (b) the application must include the following—

[s 63]

---

- (i) details of the proposed infrastructure;
  - (ii) an assessment of the impact of constructing the infrastructure on—
    - (A) the supply of water managed under the interim resource operations licences for the water supply schemes; and
    - (B) existing water entitlements to take unsupplemented water from the areas of the water supply schemes; and
    - (C) the operating arrangements and supply arrangements under the interim resource operations licences for the water supply schemes; and
    - (D) other existing authorisations, other than water permits, that may be affected by the proposed infrastructure;
  - (iii) the applicant’s proposal for minimising the impact assessed and mentioned in subparagraph (ii);
  - (iv) proposed operating arrangements for the infrastructure;
  - (v) the entities to whom the applicant proposes to supply water;
  - (vi) the applicant’s proposal about the total interim water allocation to be managed under the proposed interim resource operations licence or proposed amended interim resource operations licence; and
- (c) the application must be accompanied by the fee prescribed under a regulation.
- (4) In addition to the information mentioned in subsection (3), the applicant may give the chief executive any other information the applicant considers will help the chief executive to decide the application.

- 
- (5) To help the chief executive decide the application, the chief executive may give a copy of the application to any entity the chief executive considers appropriate.
  - (6) In this section—  
*water supply scheme* means a supplemented scheme managed under an interim resource operations licence.

**64 Additional information may be required**

- (1) The chief executive may, by notice given to the applicant, require—
  - (a) the applicant to give additional information about the application; or
  - (b) any information included in the application, or any additional information required under paragraph (a), to be verified by statutory declaration.
- (2) If the applicant does not comply with the requirement within the reasonable time stated in the notice, the application lapses.

**65 Matters chief executive must consider**

- (1) For deciding the application, the chief executive must consider—
  - (a) the application and any additional information given about the application under section 64; and
  - (b) the public interest.
- (2) Subsection (1) does not limit the matters the chief executive may consider.

**66 Deciding application for, or to amend, interim resource operations licence**

- (1) If, after deciding the application, the chief executive is satisfied the application should be approved, or approved in

[s 67]

---

part, the chief executive must approve all or part of the application, with or without conditions.

- (2) If the chief executive grants or amends the interim resource operations licence, the chief executive must reserve, from the strategic water infrastructure reserve, unallocated water required for any interim water allocations to which the approval applies.

### **Subdivision 3      Amendment by chief executive**

#### **67      Amending interim resource operations licence by chief executive—Act, s 184A**

- (1) The chief executive may—
  - (a) amend an interim resource operations licence, granted or amended under section 66, to the extent the chief executive considers necessary to meet future water requirements; or
  - (b) amend any other interim resource operations licence, to the extent the chief executive considers necessary as a consequence of—
    - (i) the granting or amendment of an interim resource operations licence under section 66; or
    - (ii) the amendment of an interim resource operations licence under section 73.
- (2) Before the chief executive acts under subsection (1), the chief executive must give the interim resource operations licence holder notice of the proposed amendment.
- (3) The notice must—
  - (a) state the following—
    - (i) a summary of the proposed amendment;
    - (ii) the reasons for the proposed amendment;

- (iii) that written submissions may be made by the holder about the proposed amendment;
- (iv) the day by which, the person to whom, and the place where, the submissions must be made; and
- (b) include a copy of the proposed amendment.
- (4) The day for written submissions must be at least 30 business days after the day the notice is given.

**68 Matters chief executive must consider**

- (1) In deciding whether to amend an interim resource operations licence under section 67, the chief executive must consider—
  - (a) the following—
    - (i) for an amendment mentioned in section 67 (1)(a)—the original application under section 63 for, or to amend, the licence and any additional information given to the chief executive about the application under section 63(4);
    - (ii) for an amendment mentioned in section 67(1)(b)(i) as a consequence of the granting or amendment of an interim resource operations licence under section 66—the application made under section 63 for the granting or amendment and any additional information given to the chief executive about the application under section 63(4);
    - (iii) for an amendment mentioned in section 67 (1)(b)(ii) as a consequence of the amendment of an interim resource operations licence under section 73—the application made under section 70 for the amendment and any additional information given to the chief executive about the application under section 71(1)(a); and
  - (b) any written submissions made by the interim resource operations licence holder about the proposed amendment; and

[s 69]

---

- (c) the public interest.
- (2) Subsection (1) does not limit the matters the chief executive may consider.

**69 Deciding whether to amend interim resource operations licence**

After considering the matters mentioned in section 68, the chief executive may amend the interim resource operations licence to the extent the chief executive considers necessary.

**Subdivision 4 Amendment on application by holder**

**70 Amending interim resource operations licence on application by holder—Act, s 184A**

- (1) The holder of an interim resource operations licence, granted or amended under section 66, may apply to the chief executive to amend the licence.
- (2) The application must—
  - (a) be in the approved form; and
  - (b) include a summary of the amendment required and the reasons for the amendment; and
  - (c) be accompanied by the fee prescribed under a regulation.
- (3) To help the chief executive decide the application, the chief executive may give a copy of the application to any entity the chief executive considers appropriate.

**71 Additional information may be required**

- (1) The chief executive may, by notice given to the applicant, require—

- 
- (a) the applicant to give the chief executive additional information about the application; or
  - (b) any information included in the application, or any additional information required under paragraph (a), to be verified by statutory declaration.
- (2) If the applicant does not comply with the requirement within the reasonable time stated in the notice, the application lapses.

**72 Matters chief executive must consider**

- (1) In deciding the application, the chief executive must consider—
  - (a) the application and any additional information given under section 71; and
  - (b) the public interest.
- (2) Subsection (1) does not limit the matters the chief executive may consider.

**73 Deciding application to amend interim resource operations licence**

If, after deciding the application, the chief executive is satisfied the application should be approved, or approved in part, the chief executive must approve all or part of the application, with or without conditions.

**Subdivision 5 Granting interim water allocations**

**74 Granting interim water allocations—Act, s 189**

- (1) This section applies if, at the time an interim resource operations licence is amended under section 66, 69 or 73, the chief executive is satisfied—
  - (a) construction of the infrastructure to which the interim resource operations licence relates is substantially

[s 74]

---

- complete and the infrastructure may be regarded as operational; and
  - (b) the operation of the infrastructure is, or will be, consistent with the outcomes and objectives of this plan; and
  - (c) the holder of the interim resource operations licence has complied with the conditions of the licence in relation to the infrastructure.
- (2) The chief executive may, by notice given to the holder of the interim resource operations licence, require the holder to give the chief executive the following information—
- (a) the number of interim water allocations to which the interim resource operations licence is to relate;
  - (b) the volume of water that may be taken under each allocation;
  - (c) the purpose for which the water may be taken;
  - (d) the priority group to which each allocation is to belong;
  - (e) the water sharing rules that are to apply.
- (3) After considering the information mentioned in subsection (2), the chief executive may grant the interim water allocations to which the interim resource operations licence relates.
- (4) This section does not apply to the amendment of another interim resource operations licence under section 69 as a consequence of—
- (a) the granting or amendment of an interim resource operations licence under section 66; or
  - (b) the amendment of an interim resource operations licence under section 73.

---

**Division 4                      Interference with water in a  
 watercourse, lake or spring**

**75            Application of div 4**

This division applies to applications, made under section 206 of the Act, for a water licence to interfere with water in a watercourse, lake or spring by impounding the flow of water.

**76            Limitations on interference with water**

- (1) The water licence may be granted if the purpose of the proposed impoundment is only 1 or more of the following—
  - (a) to store water for stock or domestic purposes;
  - (b) to provide a pumping pool to enable water to be taken under an authorisation;
  - (c) to provide improved security for town water supplies taken under an authorisation;
  - (d) to satisfy the requirements of an environmental authority issued under the *Environmental Protection Act 1994*.
- (2) However, the water licence may also be granted if—
  - (a) the proposed impoundment is related to a proposed water licence to take water that is allocated under section 36 or the process mentioned in section 48(1); or
  - (b) the impoundment was in existence immediately before 31 December 1999.

**77            Interference with water for stock or domestic purposes**

- (1) This section applies if the proposed interference with water is to store water for stock or domestic purposes.
- (2) In deciding the application the chief executive must consider the following—

[s 78]

---

- (a) existing water supplies on the property to which the application relates, including existing weirs, groundwater and storages taking overland flow water and the availability of water at the proposed site;
- (b) the matters mentioned in section 27(1)(d)(i) to (xiv).
- (3) However, the storage capacity must not be greater than is necessary for stock or domestic purposes.
- (4) Subsection (2) does not limit the matters the chief executive may consider.

**78 Interference with water for the provision of a pumping pool**

- (1) This section applies if the proposed interference with water is to provide a pumping pool to enable water to be taken under an authorisation.
- (2) The proposed storage capacity of the pumping pool must not be greater than the capacity required to enable the pump to function properly while minimising the impact the proposed interference may have on the matters mentioned in section 27(1)(d)(i) to (xiv).
- (3) However, the storage capacity of the pumping pool must not be greater than 5ML.
- (4) In deciding the application the chief executive must also consider any alternative methods for providing for the operation of the pump that may minimise the impact mentioned in section 27(1)(d)(i) to (xiv).

*Example—*

a pump well constructed in bedsand

**79 Interference with water for town water supply under an authorisation**

- (1) This section applies if the proposed interference with water is to provide improved security for town water supplies taken under an authorisation.
- (2) The chief executive must not grant the application unless the chief executive is satisfied—
  - (a) the town has appropriate water supply security strategies, such as demand and drought management strategies, in place; and
  - (b) there is a demonstrated need for an increased reliability of the water supply.
- (3) In deciding the application the chief executive must consider the matters mentioned in section 27(1)(d)(i) to (xiv).
- (4) Subsection (3) does not limit the matters the chief executive may consider.

**80 Interference with water to satisfy the requirements of an environmental authority**

- (1) This section applies if the proposed interference with water is to satisfy the requirements of an environmental authority issued under the *Environmental Protection Act 1994*.
- (2) In deciding the application the chief executive must consider the matters mentioned in section 27(1)(d)(i) to (xiv).
- (3) Subsection (2) does not limit the matters the chief executive may consider.

**81 Interference with water related to the granting of unallocated water**

- (1) This section applies if the proposed interference with water is related to the granting of unallocated water.
- (2) The interference must not be greater than is necessary for the purpose of taking the unallocated water.

[s 82]

---

- (3) In deciding the application, the chief executive must consider the matters mentioned in section 27(1)(d)(i) to (xiv).
- (4) A water licence to interfere with water, granted in association with a water entitlement to take water granted from the release of unallocated water, may include flow conditions.

## **Division 5                    Granting particular water licences**

### **82            Granting particular water licences**

- (1) The chief executive may allocate water under a water licence to take water that could have been taken under an authority issued under the *Water Act 1926–1983*, section 4.
- (2) However, a grant of water under subsection (1) to the State of Queensland, represented by the Department of Education, to take water from Gogango Creek, is subject to the limitations—
  - (a) mentioned in schedule 9, item 1, column 2; and
  - (b) imposed by the chief executive in granting a water licence for taking water under section 212 of the Act.

### **83            Granting particular water licences to holder of mining lease 1804**

- (1) The holder of mining lease 1804 is allocated water under a water licence to take water from an impoundment created by prescribed existing works if the holder gives the chief executive—
  - (a) notice, in the approved form, of any prescribed existing works after the commencement of this plan; and
  - (b) if the chief executive asks for additional information about the prescribed existing works—the additional information requested by the chief executive within a reasonable period of time as stated in the request.

- (2) However, a grant of water under subsection (1) is subject to the limitations—
- (a) mentioned in schedule 9, item 2, column 2; and
  - (b) imposed by the chief executive in granting a water licence for taking water under section 212 of the Act.
- (3) In this section—
- prescribed existing works* means works authorised under water licence number 38931F.

**Division 6                      Existing water allocations to take supplemented and unsupplemented water**

**84            Purpose of div 6**

This division states strategies for water allocations established under the repealed *Water Resource (Fitzroy Basin) Plan 1999* to take supplemented or unsupplemented water.

**85            Existing water allocations to take supplemented water**

On the commencement of this plan, a water allocation established under the repealed *Water Resource (Fitzroy Basin) Plan 1999* to take supplemented water—

- (a) is to be transitioned, without amendment, to a water allocation under this plan; and
- (b) continues to be—
  - (i) managed under the allocation’s respective resource operations licence; and
  - (ii) subject to the water sharing rules, water allocation change rules and seasonal water assignment arrangements in the resource operations plan.

[s 86]

---

**86 Existing water allocations to take unsupplemented water**

- (1) On the commencement of this plan, a water allocation established under the repealed *Water Resource (Fitzroy Basin) Plan 1999* to take unsupplemented water—
  - (a) is to be transitioned, with the amendments mentioned in subsection (2), to a water allocation under this plan; and
  - (b) continues to be subject to the water sharing rules, water allocation change rules and seasonal water assignment arrangements in the resource operations plan.
- (2) A water allocation established under the repealed *Water Resource (Fitzroy Basin) Plan 1999* to take unsupplemented water is to be amended under the resource operations plan as follows—
  - (a) to state a maximum rate for the amended water allocation equal to the rate, expressed in litres per second, stated on the existing water allocation multiplied by 1.3;
  - (b) to state a daily volumetric limit, expressed in megalitres, for the amended water allocation equal to the rate, expressed in litres per second, stated on the existing water allocation multiplied by 0.0864.

**Division 7                      Converting authorisations to water allocations to take unsupplemented water**

**87 Purpose of div 7**

This division states strategies for authorisations to be converted, under section 121 of the Act, to water allocations to take unsupplemented water under the resource operations plan.

**88 Authorisations to be converted to water allocations**

The authorisations to be converted to water allocations to take unsupplemented water are water licences for taking unsupplemented water from—

- (a) the Nogoia River from the upstream limit of Fairbairn Dam at AMTD 737.5km to its junction with Theresa Creek; and
- (b) Theresa Creek from its junction with Retreat Creek at AMTD 15.0km to its junction with the Nogoia River; and
- (c) Retreat Creek, including anabranches, from its junction with Kettle Creek at AMTD 23.6km to its junction with Theresa Creek; and
- (d) the Comet River, including anabranches, from Lake Brown gauging station AMTD 199.2km to its junction with the Nogoia River; and
- (e) the Dawson River from the upstream limit of Glebe Weir at AMTD 356.5km to its junction with the Mackenzie River, including sections of tributaries where Dawson River flows are accessible; and
- (f) the Dawson River from Utopia Downs Gauging Station at AMTD 453.5km to the upstream limit of Glebe Weir at AMTD 356.5km, including sections of tributaries where Dawson River flows are accessible.

**89 Elements of water allocations**

- (1) A water allocation to take unsupplemented water is to state the following—
  - (a) the location from which water may be taken under the allocation;
  - (b) the purpose for which water may be taken under the allocation;
  - (c) the nominal volume for the allocation;

[s 90]

---

- (d) the maximum rate at which water may be taken under the allocation;
  - (e) the daily volumetric limit for the allocation;
  - (f) the annual volumetric limit for the allocation;
  - (g) the flow conditions for the allocation;
  - (h) the water allocation group to which the allocation belongs;
  - (i) the water management area, as defined in the resource operations plan, that includes the location from which water may be taken under the allocation.
- (2) A water allocation may also state a monthly volumetric limit.

**90 Water allocation groups**

- (1) This section applies to an authorisation converted to a water allocation to take unsupplemented water (the *resulting water allocation*) mentioned in section 88.
- (2) The water allocation group for the resulting water allocation is stated in schedule 11, table, column 3 opposite the location used for taking water stated in schedule 11, table, column 1 and the flow condition stated in schedule 11, table, column 2.

**91 Location for taking water under a water allocation**

The location for taking water to be stated on a water allocation to take unsupplemented water is to include the place at which water could have been taken under the authorisation from which the allocation was converted.

**92 Purpose to be stated on a water allocation**

The purpose to be stated on a water allocation to take unsupplemented water is to be—

- (a) if the purpose stated on the authorisation is stock, domestic, irrigation, stock intensive, agriculture or a similar purpose—‘agriculture’; or
- (b) otherwise—‘any’.

**93 Nominal volume for a water allocation**

In deciding the nominal volume for a water allocation to take unsupplemented water, the chief executive must have regard to the following—

- (a) the local availability of water;
- (b) the conditions under which water may be taken under the authorisation;
- (c) for an authorisation that states any volumetric limits—the stated volumetric limits;
- (d) the simulated mean annual diversion for the proposed water allocation.

**94 Maximum rate for taking water**

- (1) The maximum rate at which water may be taken under a water allocation is—
  - (a) for an authorisation that states an authorised activity referring to the capability of a particular pump size to take water—
    - (i) for a pump size mentioned in schedule 10, column 1—the rate stated in schedule 10, column 2 for the pump size; or
    - (ii) for a pump size other than a pump size mentioned in schedule 10, column 1—the rate decided by the chief executive having regard to the rates stated for similar pump sizes in schedule 10, column 2; and
  - (b) for an authorisation that does not state an authorised activity referring to the capability of a particular pump

[s 94]

---

- size to take water, but for which a related development permit—
- (i) states a pump size mentioned in schedule 10, column 1—the rate stated in schedule 10, column 2 for the pump size; or
  - (ii) states a pump size other than a pump size mentioned in schedule 10, column 1—the rate decided by the chief executive having regard to the rates stated for similar pump sizes in schedule 10, column 2; and
- (c) for another authorisation—the rate decided by the chief executive having regard to—
- (i) the type of authorisation; and
  - (ii) an estimate or measurement of the rate at which water can be taken under the authorisation.
- (2) However, for subsection (1)(a) and (b), if the authorisation holder satisfies the chief executive that the maximum rate at which water can be taken is different from the rate under the subsection, the maximum rate is the rate decided by the chief executive having regard to the following—
- (a) the conditions under which the water may be taken;
  - (b) the water-taking capacity of the pump to which the authorised activity or development permit relates (the *existing pump*);
  - (c) the irrigation or water distribution system related to the existing pump during the period of not more than 10 years immediately before the commencement of this plan;
  - (d) the efficiency of the water use associated with the existing pump or the system mentioned in paragraph (c).
- (3) The chief executive must ensure that the total volume that can be taken in a day at the maximum rate for the allocation is not less than the daily volumetric limit under section 95.

**95 Daily volumetric limit for a water allocation**

- (1) The daily volumetric limit for a water allocation to take unsupplemented water is—
- (a) for an authorisation that states a maximum rate, expressed in litres per second—the volume, expressed in megalitres, calculated by multiplying the stated rate by 0.0864; or
  - (b) for an authorisation that does not state a maximum rate but states an authorised activity referring to the capability of a particular pump size to take water—
    - (i) for a pump size mentioned in schedule 10, column 1—the volume stated in schedule 10, column 3 for the pump size; or
    - (ii) for a pump size other than a pump size mentioned in schedule 10, column 1—the volume decided by the chief executive having regard to the volumes stated for similar pump sizes in schedule 10, column 3; or
  - (c) for an authorisation that does not state a maximum rate or an authorised activity referring to the capability of a particular pump size to take water, but for which a related development permit—
    - (i) states a pump size mentioned in schedule 10, column 1—the volume stated in schedule 10, column 3 for the pump size; or
    - (ii) states a pump size other than a pump size mentioned in schedule 10, column 1—the volume decided by the chief executive having regard to the volumes stated for similar pump sizes in schedule 10, column 3; or
  - (d) for another authorisation—the volume decided by the chief executive having regard to—
    - (i) the type of authorisation; and

[s 96]

---

- (ii) an estimate or measurement of the daily rate at which water can be taken under the authorisation.
- (2) However, for subsection (1)(b) and (c), if the authorisation holder satisfies the chief executive that the water-taking capacity of the pump is different from the daily volumetric limit under the subsection, the daily volumetric limit is the volume decided by the chief executive having regard to the following—
  - (a) the conditions under which the water may be taken;
  - (b) the water-taking capacity of the pump to which the authorised activity or development permit relates (the *existing pump*) under normal operating conditions;
  - (c) the irrigation or water distribution system related to the existing pump during the period of not more than 10 years immediately before the commencement of this plan;
  - (d) the efficiency of the water use associated with the existing pump or the system mentioned in paragraph (c).

**96 Annual volumetric limit for a water allocation**

The annual volumetric limit for a water allocation to take unsupplemented water is—

- (a) for an authorisation converted to a water allocation belonging to water allocation group Class 0A—the stated volume; or
- (b) for an authorisation converted to a water allocation belonging to water allocation group Class 9A, Class 9B, Class 10A, Class 10B, Class 11A, Class 11B, Class 12A or Class 13A—the volume, expressed in megalitres, calculated by multiplying the daily volumetric limit under section 95, by the number of days stated in schedule 11, column 4 for the water allocation group; or

- (c) for an authorisation converted to a water allocation belonging to water allocation group Class 8A, Class 10C or Class 13C—
  - (i) for an authorisation that states the area that may be irrigated—the volume, expressed in megalitres, calculated by multiplying the area, in hectares, by 6; or
  - (ii) for another authorisation—the volume, expressed in megalitres, calculated by multiplying the daily volumetric limit under section 95, by the number of days stated in schedule 11, column 4 for the water allocation group.

**97 Conditions for water allocations**

- (1) The chief executive may impose on a water allocation to take unsupplemented water any condition the chief executive is satisfied is necessary to ensure the outcomes of this plan are achieved.
- (2) In deciding the flow conditions under which water may be taken under the allocation, the chief executive must have regard to the conditions stated on the authorisation from which the allocation was converted.

**98 Monthly volumetric limit for a water allocation**

- (1) A water allocation converted from an authorisation that states an area that may be irrigated may also state a monthly volumetric limit.
- (2) The monthly volumetric limit for the water allocation is the volume decided by the chief executive having regard to the volume of water required for the allocation’s intended purpose, but not more than the volume, expressed in megalitres, calculated by multiplying the area, in hectares, by 2.

[s 99]

---

**99 Storing water taken under a water allocation**

- (1) This section applies if the chief executive decides to impose a condition on a water allocation that states works that may be used to store the water taken under the allocation.
- (2) In deciding to impose the condition, the chief executive must consider the capacity of any existing overland flow works being used to store the water.

**Division 8 Water licences to take water from watercourse, lake or spring**

**Subdivision 1 Form of water licences to take water from watercourse, lake or spring**

**100 Elements of water licences to take water from a watercourse, lake or spring**

A water licence to take water from a watercourse, lake or spring in the plan area is to state—

- (a) 1 of the following purposes for which the water may be taken under the licence—
  - (i) stock and domestic;
  - (ii) agriculture;
  - (iii) any; and
- (b) the maximum rate at which the water may be taken under the licence; and
- (c) the daily volumetric limit for the licence; and
- (d) the nominal entitlement for the licence; and
- (e) the monthly volumetric limit, if any, for the licence; and

- (f) the conditions, if any, for the licence, including flow conditions and conditions for storing water taken under the licence.

## **Subdivision 2      Criteria for amending water entitlements to achieve plan outcomes**

### **101      Definition for sdiv 2**

In this subdivision—

*amended water licence* means a water licence to take unsupplemented water from a watercourse, lake or spring and amended under section 217 of the Act.

### **102      Purpose to be stated on a water licence**

The purpose stated on an amended water licence is to be—

- (a) if the purpose stated on the water licence before the amendment is stock or domestic—‘stock and domestic’; or
- (b) if the purpose stated on the water licence before the amendment is agriculture, irrigation, stock intensive or a similar purpose—‘agriculture’; or
- (c) otherwise—‘any’.

### **103      Maximum rate for a water licence**

- (1) The maximum rate at which unsupplemented water may be taken under an amended water licence is—
  - (a) for an amended water licence that, before the amendment, stated both a maximum rate, expressed in litres per second, and a daily volumetric limit—the maximum rate stated on the licence before the amendment; or

[s 103]

---

- (b) for an amended water licence that, before the amendment, did not state a maximum rate and a daily volumetric limit but stated an authorised activity referring to the capability of a particular pump size to take water—
    - (i) for a pump size mentioned in schedule 10, column 1—the rate stated in schedule 10, column 2 for the pump size; or
    - (ii) for a pump size other than a pump size mentioned in schedule 10, column 1—the rate decided by the chief executive having regard to the rates stated for similar pump sizes in schedule 10, column 2; and
  - (c) for an amended water licence that, before the amendment, did not state a maximum rate and a daily volumetric limit or an authorised activity referring to the capability of a particular pump size to take water, but for which a related development permit—
    - (i) stated a pump size mentioned in schedule 10, column 1—the rate stated in schedule 10, column 2 for the pump size; or
    - (ii) stated a pump size other than a pump size mentioned in schedule 10, column 1—the rate decided by the chief executive having regard to the rates stated for similar pump sizes in schedule 10, column 2; and
  - (d) for another amended water licence—the rate decided by the chief executive having regard to—
    - (i) the type of licence; and
    - (ii) an estimate or measurement of the rate at which water can be taken under the licence.
- (2) However, for subsection (1)(b) and (c), if the licence holder satisfies the chief executive that the maximum rate at which water can be taken is different from the rate under the subsection, the maximum rate is the rate decided by the chief executive having regard to the following—

- (a) the conditions under which the water may be taken;
  - (b) the water-taking capacity of the pump (the *existing pump*) to which the authorised activity or development permit relates;
  - (c) the irrigation or water distribution system related to the existing pump during the period of not more than 10 years immediately before the commencement of this plan;
  - (d) the efficiency of the water use associated with the existing pump or the system mentioned in paragraph (c).
- (3) The chief executive must ensure that the total volume that could be taken in a day at the maximum rate for the amended water licence is not less than the daily volumetric limit under section 104.

**104 Daily volumetric limit for a water licence**

- (1) The daily volumetric limit for an amended water licence to take unsupplemented water is—
- (a) for an amended water licence that, before the amendment, stated the volume of water that may be taken in a day—the daily volume stated on the licence before the amendment; or
  - (b) for an amended water licence that, before the amendment, did not state a volume of water that may be taken in a day but stated a maximum rate, expressed in litres per second—the volume, expressed in megalitres, calculated by multiplying the stated maximum rate by 0.0864; or
  - (c) for an amended water licence that, before the amendment, did not state a volume of water that may be taken in a day or a maximum rate but stated an authorised activity referring to the capability of a particular pump size to take water—

[s 104]

---

- (i) for a pump size mentioned in schedule 10, column 1—the volume stated in schedule 10, column 3 for the pump size; or
  - (ii) for a pump size other than a pump size mentioned in schedule 10, column 1—the volume decided by the chief executive having regard to the volumes stated for similar pump sizes in schedule 10, column 3; or
- (d) for an amended water licence that, before the amendment, did not state a volume of water that may be taken in a day or a maximum rate or an authorised activity referring to the capability of a particular pump size to take water, but for which a related development permit—
- (i) stated a pump size mentioned in schedule 10, column 1—the volume stated in schedule 10, column 3 for the pump size; or
  - (ii) stated a pump size other than a pump size mentioned in schedule 10, column 1—the volume decided by the chief executive having regard to the volumes stated for similar pump sizes in schedule 10, column 3; or
- (e) for another amended water licence—the volume decided by the chief executive having regard to—
- (i) the type of licence; and
  - (ii) an estimate or measurement of the daily rate at which water can be taken under the licence.
- (2) However, for subsection (1)(c) and (d), if the licence holder satisfies the chief executive that the water-taking capacity of the pump is different from the daily volumetric limit under the subsection, the daily volumetric limit is the volume decided by the chief executive having regard to the following—
- (a) the conditions under which the water may be taken;

- (b) the water-taking capacity of the pump (the *existing pump*) to which the authorised activity or development permit relates under normal operating conditions;
- (c) the irrigation or water distribution system related to the existing pump during the period of not more than 10 years immediately before the commencement of this plan;
- (d) the efficiency of the water use associated with the existing pump or the system mentioned in paragraph (c).

**105 Nominal entitlement for a water licence**

The nominal entitlement for an amended water licence to take unsupplemented water is—

- (a) for an amended water licence that, before the amendment, stated the volume of water that may be taken in a 12-month period—the stated volume; or
- (b) for an amended water licence that, before the amendment, stated an area that may be irrigated—
  - (i) the volume decided by the chief executive having regard to the volume of water required for the licence’s intended purpose, but not more than the volume, expressed in megalitres, calculated by multiplying the area, expressed in hectares, by 6; or
  - (ii) if the chief executive is satisfied that the amount under subparagraph (i) is not sufficient, the volume decided by the chief executive having regard to the following—
    - (A) the volume required for the licence’s intended purpose;
    - (B) the annual volumes of water estimated by the chief executive to have been taken under the licence during the period, of not more than

[s 106]

---

10 years, immediately before the commencement of this plan;

(C) the efficiency of the use of the water mentioned in sub-subparagraph (B); or

(c) otherwise—the volume decided by the chief executive having regard to the following—

(i) the conditions under which water may be taken under the licence;

(ii) the water-taking capacity of any works for taking water under the licence;

(iii) the volume required for the licence’s intended purpose;

(iv) the annual volumes of water estimated by the chief executive to have been taken under the licence during the period, of not more than 10 years, immediately before the commencement of this plan;

(v) the efficiency of the use of the water mentioned in subparagraph (iv).

**106 Monthly volumetric limit for a water licence**

(1) This section applies to an amended water licence that, before the amendment, stated an area that may be irrigated.

(2) The monthly volumetric limit for the amended water licence is the volume decided by the chief executive having regard to the volume of water required for the licence’s intended purpose, but not more than the volume, expressed in megalitres, calculated by multiplying the area, expressed in hectares, by 2.

**107 Conditions for water licences**

In deciding the conditions, including flow conditions under which water may be taken under an amended water licence,

the chief executive must consider the conditions stated on the water licence being amended.

**108 Storing water taken under a water licence**

- (1) This section applies if the chief executive decides to impose a condition on an amended water licence that states the works that may be used to store the water taken under the licence.
- (2) In deciding to impose the condition, the chief executive must consider the capacity of any existing overland flow works being used to store the water.

**Division 9 Regulating overland flow water**

**109 Limitation on taking overland flow water—Act, s 20(6)**

- (1) This section limits the overland flow water that may be taken under section 20(6) of the Act.
- (2) A person may only take overland flow water—
  - (a) for stock or domestic purposes; or
  - (b) for another purpose, other than ponded pasture and water spreading, if the works that allow the taking of overland flow water have a capacity of not more than 50ML; or
  - (c) under a water licence; or
  - (d) of not more than the amount necessary to satisfy the requirements of the following—
    - (i) an environmental authority issued under the *Environmental Protection Act 1994*;
    - (ii) a development permit for carrying out an environmentally relevant activity, other than a mining or petroleum activity, under the *Environmental Protection Act 1994*; or

[s 110]

---

- (e) that is contaminated agricultural runoff water; or
- (f) of a volume that is incidental to the operation of a storage constructed to store coal seam gas water for which an entity holds an approval under the *Environmental Protection (Waste Management) Regulation 2000*, part 6A; or
- (g) under section 110.

(3) In this section—

***coal seam gas water*** see the *Environmental Protection Act 1994*, section 310D(7).

***contaminated agricultural runoff water*** means overland flow water that contains, or is likely to contain, excess nutrients or farm chemicals at levels potentially harmful to the quality of water in a watercourse.

***ponded pasture*** means a permanent or periodic pondage of water in which the dominant plant species are pasture species used for grazing or harvesting.

***water spreading*** means diverting or collecting runoff from natural channels, gullies or streams, with a system of banks, ditches or other means, and spreading it over a relatively flat area.

## 110 Taking water using particular existing overland flow works authorised

- (1) This section applies to the following—
  - (a) a person who—
    - (i) is the owner of land on which existing overland flow works are situated, other than works for taking only the overland flow water that may be taken under section 109(2)(a) to (f); and
    - (ii) did not give the chief executive notice of the existing overland flow works mentioned in subparagraph (i) under previous section 28D;

- (b) the holder of a mining lease for land on which existing overland flow works are situated, other than works for taking only the overland flow water that may be taken under section 109(2)(a) to (f).
- (2) The holder of a mining lease mentioned in subsection (1)(b) may continue to use the existing overland flow works to take overland flow water for 1 year after the commencement of this plan.
- (3) If the person, or the holder of a mining lease, gives the chief executive notice of the existing overland flow works, in the approved form, and any further information reasonably required by the chief executive about the works, the person, or holder, may continue to use the works to take overland flow water after the notice and information are given.
- (4) In this section—  
*previous section 28D* means section 28D of the repealed *Water Resource (Fitzroy Basin) Plan 1999*.

**111 Granting water licences under the resource operations plan**

- (1) This section applies if the resource operations plan states a process for granting, under section 212 of the Act, a water licence to replace an authority under section 110.
- (2) Under the process, the chief executive—
  - (a) must consider—
    - (i) the average annual volume of overland flow water that could have been taken, immediately before the commencement of this plan, using the existing overland flow works to which the authority relates; and
    - (ii) the annual volumes of overland flow water estimated by the chief executive to have been taken using the works during the period, of not more than

[s 112]

---

10 years, immediately before the commencement of this plan; and

- (b) may consider the extent to which the works, immediately before the commencement of this plan, allowed—
  - (i) the taking of other water under another authorisation; or
  - (ii) the storage of other water taken under another authorisation.
- (3) Subsection (2) does not limit the matters the chief executive may consider.
- (4) The process may require the authority or licence holder to give the chief executive a certificate, from a registered professional engineer, stating information about the works including the capacity of the works and the rate at which the works may take water.
- (5) In this section—

*registered professional engineer* means a person registered as a registered professional engineer under the *Professional Engineers Act 2002*.

## 112 Water licences to take overland flow water

A water licence to take overland flow water is to state—

- (a) 1 of the following purposes for which water may be taken under the licence—
  - (i) agriculture;
  - (ii) any; and
- (b) at least 1 of the following—
  - (i) the maximum rate at which water may be taken under the licence;
  - (ii) the daily volumetric limit for the licence;

- (iii) the nominal entitlement for the licence;
- (iv) the maximum volume of water that may be stored under the licence; and
- (c) the conditions, if any, for the licence.

**113 Relationship with Sustainable Planning Act 2009**

- (1) Works that allow the taking of overland flow water are assessable development for the *Sustainable Planning Regulation 2009*, schedule 3, part 1, table 4, item 3(c)(i).
- (2) Subsection (1) does not apply to—
  - (a) works mentioned in subsection (3); or
  - (b) the repair or maintenance of either of the following works if the repair or maintenance does not alter the design of the works—
    - (i) existing overland flow works mentioned in section 110;
    - (ii) works constructed under a development permit.
- (3) The following works that allow the taking of overland flow water are self-assessable development for the *Sustainable Planning Regulation 2009*, schedule 3, part 2, table 4, item 1(b)(ii)—
  - (a) works for taking overland flow water only for stock or domestic purposes;
  - (b) works mentioned in section 109(2)(b);
  - (c) works for taking only the overland flow water mentioned in section 109(2)(d).

[s 114]

---

## **Part 3 Additional strategies for groundwater**

### **Division 1 Preliminary**

#### **114 Application and purpose of pt 3**

This part—

- (a) applies only to groundwater in a groundwater management area; and
- (b) states the strategies for achieving the outcomes mentioned in chapter 3.

#### **115 Limitation on taking or interfering with groundwater—Act, s 20(6)**

- (1) This section limits the groundwater that may be taken or interfered with under section 20(6) of the Act.
- (2) A person may only take or interfere with groundwater in a groundwater management area—
  - (a) under a water permit; or
  - (b) under a water licence; or
  - (c) under an interim water allocation; or
  - (d) under a water allocation; or
  - (e) under section 123; or
  - (f) for stock or domestic purposes.

#### **116 Relationship with Sustainable Planning Act 2009**

- (1) In the Carnarvon groundwater management area, all works for taking groundwater are assessable development for the *Sustainable Planning Regulation 2009*, schedule 3, part 1, table 4, item 3(c)(ii).

- 
- (2) In a groundwater management area other than the Carnarvon groundwater management area—
    - (a) works for taking groundwater for other than stock or domestic purposes are assessable development for the *Sustainable Planning Regulation 2009*, schedule 3, part 1, table 4, item 3(c)(ii); and
    - (b) works for taking groundwater for stock or domestic purposes are self-assessable development for the *Sustainable Planning Regulation 2009*, schedule 3, part 2, table 4, item 1(b)(iii).

## **Division 2            Water licences to take groundwater**

### **Subdivision 1        General**

#### **117    Elements of water licences**

- (1) A water licence to take groundwater is to state the following—
  - (a) 1 of the following purposes for which the water may be taken under the licence—
    - (i) agriculture;
    - (ii) any;
  - (b) the nominal entitlement for the licence;
  - (c) the conditions, if any, for the licence.
- (2) However, subsection (1) does not apply to a licence for mine dewatering granted under section 206 of the Act.

[s 118]

---

**Subdivision 2      Criteria for amending water entitlements to achieve plan outcomes**

**118      Definition for sdiv 2**

In this subdivision—

*amended water licence* means a water licence to take groundwater and amended under section 217 of the Act.

**119      Purpose to be stated on a water licence**

The purpose stated on an amended water licence is to be—

- (a) if the purpose stated on the water licence is agriculture, irrigation, stock intensive or a similar purpose—‘agriculture’; or
- (b) otherwise—‘any’.

**120      Nominal entitlement for a water licence**

The nominal entitlement for an amended water licence is—

- (a) for a water licence that, before the amendment, states the volume of water that may be taken in a 12-month period—the stated volume; and
- (b) otherwise—the volume decided by the chief executive having regard to the following—
  - (i) the conditions under which water may be taken under the licence;
  - (ii) the water-taking capacity of any works for taking water under the licence;
  - (iii) the volume required for the licence’s intended purpose;
  - (iv) the annual volumes of water estimated by the chief executive to have been taken under the licence

during the period, of not more than 10 years, immediately before the commencement of this plan;

- (v) the efficiency of the use of the water mentioned in subparagraph (iv).

**121 Conditions for water licences**

In deciding the conditions under which water may be taken under an amended water licence, the chief executive must consider the conditions stated on the water licence being amended.

**Subdivision 3 Dealing with particular existing groundwater works**

**122 Definition for sdiv 3**

In this subdivision—

*prescribed existing groundwater works* means works the chief executive is satisfied were used or capable of being used to take groundwater for a purpose, other than stock or domestic purposes, from the—

- (a) Isaac Connors Groundwater Unit 1 in the Isaac Connors groundwater notification area and the works were in existence on 15 December 2006; or
- (b) Isaac Connors Groundwater Unit 2 in the Isaac Connors groundwater notification area and the works were in existence on the 2010 moratorium publication day; or
- (c) Callide groundwater notification area and the works were in existence on the 2010 moratorium publication day.

[s 123]

---

**123 Taking groundwater using prescribed existing groundwater works**

- (1) This section applies to an owner of land on which there are prescribed existing groundwater works.
- (2) The owner may continue to take groundwater using the works for 1 year after the commencement of this plan.
- (3) If the owner gives the chief executive notice in the approved form of the works within 1 year after the commencement of this plan, the owner may continue to take groundwater using the works.
- (4) However, an authorisation under this section ceases to apply to an owner in relation to prescribed existing groundwater works if the owner is granted a water licence relating to the works.

**124 Granting water licences for using prescribed existing groundwater works**

- (1) The chief executive may, under section 212 of the Act, grant a water licence to a person authorised under section 123(2) to continue taking groundwater.
- (2) The licence must be consistent with this part.

**125 Nominal entitlements for authorisations**

- (1) This section applies if the chief executive decides the nominal entitlement for a water licence mentioned in section 124.
- (2) The nominal entitlement is to be the estimated volume to take groundwater for the entitlement.
- (3) However, if the chief executive is satisfied the volume (a *higher volume*) of groundwater taken during the relevant period is more than the estimated volume, having regard to the following, the chief executive may decide a nominal entitlement that is more than the estimated volume—

- (a) the efficiency of the use of the groundwater mentioned in paragraph (c) or (d);
  - (b) the availability of groundwater in the aquifer to which the works relate;
  - (c) the availability of other water sources in the area to which the entitlement relates;
  - (d) the density of water bores for taking groundwater in the area to which the entitlement relates.
- (4) In considering whether a higher volume of groundwater was taken during the relevant period, the chief executive must consider each of the following—
- (a) the water-taking capacity of the prescribed existing groundwater works as at the commencement of this plan;
  - (b) the number of hours the works were operated during the relevant period;
  - (c) for works for irrigation purposes—the volume of groundwater estimated by the chief executive to have been taken during the relevant period for irrigating crops grown during the period;
  - (d) for works for a purpose other than irrigation purposes—the volume of groundwater estimated by the chief executive to have been taken during the relevant period for the purpose.
- (5) Subsections (3) and (4) do not limit the matters the chief executive may consider.
- (6) In this section—
- capacity**, of prescribed existing groundwater works, means—
- (a) if the water bore for the works has a design pumping rate only—the design pumping rate for the bore; or
  - (b) if the works have an equipped rate only—the equipped rate for the works; or

[s 125]

---

- (c) if the works have a design pumping rate and an equipped rate—the lesser of the design pumping rate and the equipped rate.

**design pumping rate**, for a water bore, means the pumping rate—

- (a) at which the bore can be pumped without causing the bore’s pump to break suction; and
- (b) estimated from an analysis of a pumping test based on the drawdown available in the bore above the pump inlet that would sustain pumping for 70 consecutive days.

**equipped rate**, for prescribed existing groundwater works, means the rate at which pumping equipment installed on the works can be pumped for the purposes for which the works are used.

**estimated volume**, to take groundwater for a water entitlement, means the lesser of the following—

- (a) the volume worked out by multiplying the capacity of the prescribed existing groundwater works by the number of hours, that must not be more than 2000 hours, the chief executive decides having regard to—
  - (i) the efficiency of the use of groundwater using the works during the relevant period; and
  - (ii) the availability of other water sources in the area to which the entitlement relates;
- (b) the volume of groundwater taken using the prescribed existing groundwater works for irrigation purposes during the relevant period, if the volume is not more than 6ML of water for each hectare of property.

**relevant period** means each 1 year during the period of not more than 10 years immediately before the commencement of this plan.

---

**Division 3                      Converting authorisations to water allocations to take unsupplemented groundwater**

**126      Purpose of div 3**

This division states strategies for authorisations to be converted, under section 121 of the Act, to water allocations to take unsupplemented groundwater under the resource operations plan.

**127      Definition for div 3**

In this division—

*previous authorisation* means an authorisation mentioned in section 126.

**128      Authorisations to be converted to water allocations**

The authorisations to be converted to water allocations to take unsupplemented groundwater are water licences for taking groundwater, other than for the purpose of stock, from the following sub-areas—

- (a) Upper Callide groundwater sub-area;
- (b) Lower Callide groundwater sub-area;
- (c) Prospect Creek groundwater sub-area.

**129      Elements of water allocations**

A water allocation to take unsupplemented groundwater is to state the following—

- (a) the location from which water may be taken under the allocation;
- (b) the purpose for which water may be taken under the allocation;

[s 130]

---

- (c) the nominal volume for the allocation;
- (d) the annual volumetric limit for the allocation;
- (e) the water allocation group to which the allocation belongs;
- (f) the conditions under which water may be taken under an allocation;
- (g) the groundwater management area that includes the location from which groundwater may be taken under the allocation.

**130 Location for taking water under a water allocation**

The location for taking water to be stated on a water allocation to take unsupplemented groundwater is to include the place at which water could have been taken under the previous authorisation.

**131 Purpose to be stated on a water allocation**

The purpose to be stated on a water allocation to take unsupplemented groundwater is to be—

- (a) if the purpose stated on the previous authorisation is irrigation, stock intensive, agriculture or a similar purpose—‘agriculture’; or
- (b) otherwise—‘any’.

**132 Nominal volume for a water allocation**

In deciding the nominal volume for a water allocation to take unsupplemented groundwater, the chief executive must have regard to the following—

- (a) the local availability of groundwater;
- (b) the conditions under which groundwater may be taken under the previous authorisation;

- (c) the annual volumetric limit under section 133;
- (d) the simulated mean annual diversion for the proposed water allocation.

**133 Annual volumetric limit for a water allocation**

The annual volumetric limit for a water allocation to take unsupplemented groundwater is the annual volumetric limit decided by the chief executive under section 139.

**134 Water allocation groups**

A water allocation to take unsupplemented groundwater belongs to the following water allocation groups—

- (a) for a water allocation to take unsupplemented groundwater from Upper Callide groundwater sub-area—
  - (i) for water allocations converted from water authorisations 33535X and 47301D—the GW1A water allocation group; or
  - (ii) for all other water allocations—the GW1B water allocation group;
- (b) for a water allocation to take unsupplemented groundwater from Lower Callide groundwater sub-area—
  - (i) for a water allocation converted from water authorisation 43919D—the GW2A water allocation group; or
  - (ii) for all other water allocations—the GW2B water allocation group;
- (c) for a water allocation to take unsupplemented groundwater from Prospect Creek groundwater sub-area—

[s 135]

---

- (i) for a water allocation converted from water authorisation 68275D—the GW3A water allocation group; or
- (ii) for all other water allocations—the GW3B water allocation group.

**135 Conditions for water allocations**

In deciding the conditions under which groundwater may be taken under a water allocation, the chief executive must have regard to the conditions stated on the previous authorisation, or a development permit relating to the previous authorisation.

**Division 4 Nominal volume and annual volumetric limit for new groundwater allocations**

**136 Application of div 4**

This division applies to the following—

- (a) an interim water allocation mentioned in section 51 converted under the resource operations plan to a water allocation to take supplemented water and belonging to the medium priority group as stated on the interim resource operations licence;
- (b) an authorisation mentioned in section 128 converted under section 121 of the Act to a water allocation to take unsupplemented groundwater.

**137 Purpose of div 4**

The purpose of this division is to provide for—

- (a) water allocations to be converted from interim water allocations mentioned in section 136(a)—the nominal volume for the water allocations; and

- (b) water allocations to be converted from authorisations mentioned in section 136(b)—the annual volumetric limit for the water allocations.

**138 Definitions for div 4**

In this division—

**2007 authorisation** means a prescribed authorisation in existence on 1 July 2007.

**2007 authorisation volume**, for a 2007 authorisation, see section 140.

**accounted use** means the volume of water, taken by a water user in a water year, decided by the chief executive having regard to all available information, including information from water accounts.

**annual adjusted use volume**, for a 2007 authorisation, see section 141(1).

**carry over** means a volume of water, not taken in a water year, that was authorised to be taken in the following water year.

**converting authorisation** means—

- (a) an interim water allocation mentioned in section 51; and
- (b) an authorisation mentioned in section 128.

**deemed use**, for an authorisation, means the volume of water deemed to have been taken in a water year under the authorisation.

**forward draw** means a volume of water, for a water year, that was authorised to be taken in the previous water year.

**HOU consideration period** means the period from 1 July 1997 to 30 June 2007.

**pre-2007 contributing authorisation** means a prescribed authorisation that contributed the whole or part of its nominal entitlement to a 2007 authorisation as a result of subdivision

[s 139]

---

or amalgamation, or a series of subdivisions or amalgamations.

*Examples—*

- Authorisation A is a 2007 authorisation, and is the result of the amalgamation of authorisation B and C. Authorisations B and C are pre-2007 contributing authorisations to authorisation A.
- Authorisations D and E are 2007 authorisations, and each is the result of the subdivision of authorisation F. Authorisation F is a pre-2007 contributing authorisation for authorisation D and authorisation E.

***prescribed authorisation*** means a medium priority interim water allocation or a water licence to take groundwater that existed at any time between 1 July 1997 and the day the resource operations plan is amended to convert the interim water allocations or authorisations mentioned in section 136.

***water accounts*** means the records of water taken from the Upper Callide, Lower Callide and Prospect Creek groundwater sub-areas and the Callide Valley Water Supply Scheme, as recorded in the department's, and interim resource operations licence holder's, water accounting systems.

***water year*** means a 12-month period beginning on 1 July.

**139 Nominal volume or annual volumetric limit for a water allocation**

- (1) A water allocation mentioned in section 136(a) is to have a nominal volume for the allocation.
- (2) A water allocation mentioned in section 136(b) is to have an annual volumetric limit for the allocation.
- (3) The nominal volume or annual volumetric limit of the water allocation is equal to—
  - (a) for a converting authorisation that is a 2007 authorisation that has not been subdivided, or amalgamated with another authorisation, after 1 July 2007—the lesser of—

- 
- (i) the nominal entitlement of the converting authorisation; and
  - (ii) the 2007 authorisation volume plus 5ML; or
  - (b) otherwise—the lesser of—
    - (i) the nominal entitlement of the converting authorisation; and
    - (ii) the volume calculated by the chief executive using the beneficial volumes of the post-2007 contributing authorisations that contributed to the nominal entitlement of the converting authorisation.
  - (4) When calculating the volume under subsection (3)(b)(ii), the chief executive must—
    - (a) for a post-2007 contributing authorisation in existence on [*date of the release of the draft water resource plan*]*—include an additional 5ML in the beneficial volume; and*
    - (b) if a post-2007 contributing authorisation is subdivided—apportion the beneficial volume of the subdivided authorisation between the authorisations resulting from the subdivision in the same ratio as the nominal entitlement was apportioned between the resulting authorisations; and
    - (c) if a post-2007 contributing authorisation is amalgamated—add the beneficial volumes of the authorisations that have been amalgamated.
  - (5) In this section—
 

**beneficial volume**, of a post-2007 contributing authorisation, means the volume, derived from a 2007 authorisation volume, of the post-2007 contributing authorisation as a result of the subdivision or amalgamation of—

    - (a) a 2007 authorisation; or
    - (b) another post-2007 contributing authorisation.

[s 140]

---

*Note—*

The volume is not the nominal entitlement for an authorisation.

***post-2007 contributing authorisation*** means a prescribed authorisation in existence on or after 1 July 2007, including a 2007 authorisation, that contributes, as a result of subdivision or amalgamation, or a series of subdivisions or amalgamations, to the nominal entitlement of a converting authorisation.

*Examples—*

- Authorisation A is the result of the amalgamation of authorisations B and C. Authorisations B and C are post-2007 contributing authorisations to authorisation A.
- Authorisations D and E are each the result of the subdivision of authorisation F. Authorisation F is a post-2007 contributing authorisation for authorisation D and authorisation E.

**140 2007 authorisation volume**

The volume (the ***2007 authorisation volume***) for a 2007 authorisation is the mean, rounded up to the nearest megalitre, of the five largest annual adjusted use volumes for the 2007 authorisation.

**141 Annual adjusted use volume**

- (1) The ***annual adjusted use volume*** for a 2007 authorisation for each water year in the HOU consideration period is equal to—
  - (a) for a 2007 authorisation not affected by a subdivision or amalgamation of an authorisation during the HOU consideration period—the deemed use for the 2007 authorisation for the water year as adjusted under subsection (2); or
  - (b) otherwise—the sum of the deemed use for each pre-2007 contributing authorisation in existence on the last day of the water year as adjusted under subsections (2) and (3).

- 
- (2) The deemed use for an authorisation for each water year is adjusted in the following way—
    - (a) any deemed use for the authorisation up to the amount of the announced allocation volume for the authorisation is to be attributed to the particular water year;
    - (b) after adjusting the deemed use under paragraph (a), any remaining deemed use for the authorisation up to the volume taken under a carry over is to be attributed to the water year from which the carry over was derived;
    - (c) after adjusting the deemed use under paragraph (b), any remaining deemed use for the authorisation up to the volume taken under a forward draw is to be attributed to the water year from which the forward draw was derived.
  - (3) In addition to the adjustment under subsection (2), the deemed use for an authorisation is adjusted to account for any amalgamation or subdivision of authorisations as follows—
    - (a) when adjusting for the amalgamation of authorisations—add the deemed use from all authorisations contributing to the amalgamation;
    - (b) when adjusting for the subdivision of an authorisation—apportion the deemed use between the resulting authorisations in the same ratio as the nominal entitlement of the subdivided authorisation was apportioned to the resulting authorisations.
  - (4) In this section—
 

*announced allocation volume*, for an authorisation, means the volume of water authorised to be taken in a water year under the authorisation, not including any carry over or forward draw.

**142 Deemed use for an authorisation**

- (1) The deemed use for each 2007 authorisation and pre-2007 contributing authorisation is to be calculated by the chief

[s 142]

---

executive for each water year in the HOU consideration period.

- (2) In calculating the deemed use for an authorisation, the chief executive must—
  - (a) consider the accounted use for all water users in the Upper Callide, Lower Callide and Prospect Creek groundwater sub-areas and Callide Valley Water Supply Scheme; and
  - (b) consider the volumes of water taken under a seasonal water assignment or temporary transfer arrangement; and
  - (c) disregard the volumes of water considered to be taken under a stock or domestic accounting arrangement; and
  - (d) disregard any volume of water taken that the chief executive is satisfied was not authorised to be taken under the authorisation.

- (3) In this section—

*stock or domestic accounting arrangement* means an arrangement that allows for a particular volume of water taken to be considered as water taken for stock or domestic purposes.

*temporary transfer arrangement* means an arrangement that had the same effect as seasonal water assignment and was implemented prior to the commencement of the *Water Act 2000*.

## Chapter 6      Monitoring and reporting requirements

### 143      Monitoring

- (1) The monitoring requirements for this plan are—
  - (a) water monitoring for—
    - (i) stream flows; and
    - (ii) taking and diverting water; and
    - (iii) releases from water storages; and
    - (iv) water quantity for water storages, including inflow, storage volume or level and outflow; and
    - (v) groundwater levels.
  - (b) natural ecosystems monitoring for—
    - (i) volume, frequency, duration and timing of stream flows; and
    - (ii) information on hydraulic habitat requirements of ecological assets in the plan area; and
  - (c) groundwater developments, including records of water bores drilled; and
  - (d) existing overland flow works of which the chief executive is notified under section 110(3); and
  - (e) other water and natural ecosystem monitoring required by the chief executive.
- (2) The monitoring requirements are to be achieved by—
  - (a) monitoring programs undertaken by operators of infrastructure for interfering with water under the resource operations plan; and
  - (b) monitoring programs administered by the chief executive and relevant State agencies; and

- (c) other monitoring programs considered by the chief executive to be relevant to the matters mentioned in subsection (1).

**144 Monitoring programs undertaken by operators of infrastructure**

- (1) Each operator of infrastructure for interfering with water in the plan area must develop and undertake the monitoring programs stated, for the operator, in the resource operations plan.
- (2) The monitoring programs must assist in enabling the chief executive to assess the effectiveness of the strategies under chapter 5.

**145 Operators of infrastructure to give reports**

- (1) Each operator of infrastructure for interfering with water in the plan area must, to the extent required under the resource operations plan, give the chief executive a written report containing the following information—
  - (a) details of information obtained by the monitoring programs mentioned in section 144;
  - (b) details of decisions made by the operator in managing water and water infrastructure, or distributing water, including, for example, decisions about the following—
    - (i) making water available to water users under the operator’s usual procedures for managing or distributing water;
    - (ii) managing the flow of water;
    - (iii) restricting the taking or supply of water;
    - (iv) infrastructure modifications or installations;
  - (c) information about any noncompliance by the operator with the resource operations plan;
  - (d) details about remedial action taken by the operator—

[s 146]

---

- (i) in relation to a requirement under the resource operations plan; or
  - (ii) in response to an event or thing affecting water quality;
- (e) details of any emergency action taken by the operator that may affect the achievement of the outcomes under chapter 3.
- (2) A report about a matter mentioned in subsection (1) must be given—
  - (a) for each financial year in which the operator manages or distributes water under this plan; and
  - (b) within 3 months after the end of the financial year to which the report relates.
- (3) A report about a matter mentioned in subsection (1)(e) must also be given the next business day after the action is taken.
- (4) Despite subsection (2), the resource operations plan may require reports about matters mentioned in subsection (1) to be given more frequently than for each financial year.

**146 Minister's report on plan—Act, s 53**

- (1) The Minister's report on this plan must be prepared—
  - (a) for each financial year this plan is in force; and
  - (b) within 6 months after the end of the financial year to which the report relates.
- (2) If the Minister is satisfied about any of the matters mentioned in section 149, the report, in its assessment of the effectiveness of the implementation of the plan in achieving the plan's outcomes, must include a consideration of the matters.

## Chapter 7      Implementing and amending this plan

### 147      Implementation schedule

- (1) This section states the proposed arrangements for implementing this plan.
- (2) Within 2 years after the commencement of this plan, it is proposed to amend the resource operations plan to—
  - (a) grant, or convert authorisations to, water allocations to take water in all of the priority areas; and
  - (b) for water in the Callide Valley Water Supply Scheme—make environmental management rules, infrastructure operating rules, water sharing rules, water allocation change rules and seasonal water assignment rules; and
  - (c) establish a process to grant licences to take groundwater in the Callide groundwater notification area and the Isaac Connors groundwater notification area; and
  - (d) establish a process to deal with unallocated water available for future water requirements in the plan area; and
  - (e) establish a process for granting water licences for taking overland flow water; and
  - (f) implement the monitoring requirements mentioned in chapter 6.
- (3) In this section—

***priority area*** means each of the following—

  - (a) the Callide Valley Water Supply Scheme;
  - (b) the Upper Callide, Lower Callide and Prospect Creek groundwater sub-areas in the Callide groundwater management area;
  - (c) the following parts of the Fitzroy Basin—

[s 148]

---

- (i) the Nogoia River from the upstream limit of Fairbairn Dam at AMTD 737.5km to its junction with Theresa Creek;
- (ii) Theresa Creek from its junction with Retreat Creek at AMTD 15.0km to its junction with the Nogoia River;
- (iii) Retreat Creek, including anabranches, from its junction with Kettle Creek at AMTD 23.6km to its junction with Theresa Creek;
- (iv) the Comet River, including anabranches, from Lake Brown gauging station AMTD 199.2km to its junction with the Nogoia River;
- (v) the Dawson River from the upstream limit of Glebe Weir at AMTD 356.5km to its junction with the Mackenzie River, including sections of tributaries where Dawson River flows are accessible;
- (vi) the Dawson River from Utopia Downs gauging station at AMTD 453.5km to the upstream limit of Glebe Weir at AMTD 356.5km, including sections of tributaries where Dawson River flows are accessible.

**148 Minor or stated amendment of plan—Act, s 57**

The following types of amendment may be made to this plan under section 57(b) of the Act—

- (a) an amendment or addition of an environmental flow objective if the amendment or addition achieves an equivalent or improved ecological outcome without adversely affecting—
  - (i) the outcomes mentioned in chapter 3; or
  - (ii) the water allocation security objectives mentioned in chapter 4, part 2;

- (b) an amendment or addition of a water allocation security objective if the amendment or addition does not adversely affect—
  - (i) the outcomes mentioned in chapter 3; or
  - (ii) the environmental flow objectives mentioned in chapter 4, part 1;
- (c) an amendment or addition of a node;
- (d) an amendment to subdivide a subcatchment area;
- (e) an amendment to adjust the boundaries of a groundwater management area and groundwater sub-area if more accurate information about the boundaries of the plan area or hydrological characteristics of the plan area becomes available;
- (f) an amendment or addition of a priority group;
- (g) an amendment or addition of a water allocation group;
- (h) an amendment of the capacity of works to take overland flow water mentioned in section 109(2)(b);
- (i) an amendment or addition of a monitoring or reporting requirement under chapter 6.

**149 Amending or replacing plan**

The Minister must consider amending this plan or preparing a new plan to replace this plan if the Minister is satisfied—

- (a) in relation to this plan’s general outcomes under section 12—
  - (i) water entitlements in the plan area are not sufficient to meet water needs sourced from the plan area having regard to—
    - (A) the extent to which water is being taken under the water entitlements; and
    - (B) the efficiency of present, and expected future, water use; and

[s 150]

---

- (C) emerging requirements for additional water; and
- (D) water savings that may be made from improvements in the efficiency of water use or the use of water from other sources including, for example, recycled water; and
- (E) the likely timeframe in which additional water will be required; and
- (ii) there are economically viable and ecologically sustainable uses for additional water; or
- (b) any of the following are not being achieved—
  - (i) the specific surface water and groundwater outcomes under section 13;
  - (ii) the general ecological outcomes under section 14;
  - (iii) the specific ecological outcomes under section 15.

## **Chapter 8      Repeal of the Water Resources (Fitzroy Basin) Plan 1999**

### **150      Repeal**

The Water Resources (Fitzroy Basin) Plan 1999 is repealed.

## Schedule 6 Environmental flow objectives

sections 16, 17, 19 and 23 and schedule 13, definition *base flow*

### Part 1 Seasonal base flow objectives

At each node mentioned in table 1, column 1—

- (a) for watercourses within water supply schemes—the percentage of the total number of days in a water flow season in the simulation period that the base flow, for the node, in table 1, column 2, is equalled or exceeded should be between 0.8 and 1.2 times the percentage stated for the water flow season for the node, in table 1, column 3; and
- (b) for watercourses elsewhere—the percentage of the total number of days in a water flow season in the simulation period that the base flow, for the node, in table 1, column 2, is equalled or exceeded is to be at least 0.9 times the percentage stated for the water flow season for the node, in table 1, column 3.

Table 1

Column 1	Column 2	Column 3		
Node	Base flow (ML/d)	Water flow season		
		January–April water flow season	May–August water flow season	September–December water flow season
0	288	88%	57%	47%
2	86	64%	27%	35%
3	26	43%	19%	19%
6	38	51%	26%	30%
8	190	82%	41%	37%
9	104	84%	49%	33%

Column 1	Column 2	Column 3		
Node	Base flow (ML/d)	Water flow season		
		January–April water flow season	May–August water flow season	September–December water flow season
9A	90	87%	58%	36%
10	163	54%	19%	29%
12	148	33%	10%	11%
14	104	23%	5%	7%

## Part 2 Medium to high flow objectives

- 1 At each node mentioned in table 2, column 1—
  - (a) the mean annual flow in the simulation period, expressed as a percentage of the mean annual flow for the pre-development flow pattern, is to be at least the percentage stated for the node in table 2, column 2; and
  - (b) the median annual flow ratio in the simulation period, expressed as a percentage, is to be at least the percentage stated for the node in table 2, column 3; and
  - (c) the annual proportional flow deviation is to be not more than the annual proportional flow deviation stated for the node in table 2, column 4; and
  - (d) the mean wet season flow in the simulation period, expressed as a percentage of the mean wet season flow for the pre-development flow pattern, is to be at least the percentage stated for the node in table 2, column 5.

Table 2

Column 1	Column 2	Column 3	Column 4	Column 5
Node	Mean annual flow	Median annual flow ratio	Annual proportional flow deviation	Mean wet season flow
0	77%	59%	2.3	80%
2	65%	48%	3.1	Not applicable
3	85%	85%	1.1	
6	90%	85%	0.5	
8	80%	65%	1.8	
9	90%	80%	1.1	
9A	90%	85%	1	
10	70%	50%	2.7	
12	80%	54%	1.8	
14	90%	75%	0.8	

- 2 At each node mentioned in table 3, column 1—
- (a) the 10% daily exceedance duration flow in the simulation period, expressed as a percentage of the 10% daily exceedance duration flow for the pre-development flow pattern, is to be at least the percentage stated for the node in table 3, column 2; and
  - (b) the 4% daily exceedance duration flow in the simulation period, expressed as a percentage of the 4% daily exceedance duration flow for the pre-development flow pattern, is to be at least the percentage stated for the node in table 3, column 3; and
  - (c) the 2 year daily flow volume in the simulation period, expressed as a percentage of the 2 year daily flow volume for the pre-development flow pattern, is to be at least the percentage stated for the node in table 3, column 4; and
  - (d) the 5 year daily flow volume in the simulation period, expressed as a percentage of the 5 year daily flow volume for the pre-development flow pattern, is to be at

least the percentage stated for the node in table 3, column 5; and

- (e) the 20 year daily flow volume in the simulation period, expressed as a percentage of the 20 year daily flow volume for the pre-development flow pattern, is to be at least the percentage stated for the node in table 3, column 6.

Table 3

Column 1	Column 2	Column 3	Column 4	Column 5	Column 6
Node	10% daily exceedance duration flow	4% daily exceedance duration flow	2 year daily flow volume	5 year daily flow volume	20 year daily flow volume
0	74%	55%	75%	87%	88%
2	53%	45%	55%	69%	80%
3	81%	82%	86%	89%	92%
6	81%	81%	91%	97%	98%
8	74%	57%	86%	91%	98%
9	82%	80%	76%	94%	93%
9A	87%	83%	74%	95%	90%
10	59%	45%	62%	79%	88%
12	61%	45%	60%	80%	98%
14	71%	82%	81%	95%	98%

## Part 3 First post-winter flow event objectives and performance indicators

### 1 Performance indicators

The performance indicators for the first post-winter flow event objective are the following—

- (a) the number of first post-winter flow events in the simulation period expressed as a percentage of the number of post-winter flow years in the period;
- (b) the number of 5-week lag events in the simulation period, expressed as a percentage of the number of post-winter flow years in the period;
- (c) the number of 2-week lag events in the simulation period, expressed as a percentage of the number of 5-week lag events in the period;
- (d) the average of the volume ratios for the post-winter flow years in the simulation period;
- (e) the average of the peak flow ratios for the post-winter flow years in the simulation period;
- (f) the number of 2-times base flow events in the simulation period, expressed as a percentage of the number of post-winter flow years in the period;
- (g) the number of 5-times base flow events in the simulation period, expressed as a percentage of the number of post-winter flow years in the period.

**2 First post-winter flow event objectives**

The first post-winter flow event objectives are—

- (a) first post-winter flow events that pass through dams, weirs, barrages, watercourses or lakes are to mimic the pre-development flow pattern of first post-winter flow events in duration, timing and magnitude; and
- (b) for each node mentioned in table 4, column 1—
  - (i) the performance indicator mentioned in item 1(a) is to be at least the percentage stated for the node in table 4, column 2; and
  - (ii) the performance indicator mentioned in item 1(b) is to be at least the percentage stated for the node in table 4, column 3; and

- (iii) the performance indicator mentioned in item 1(c) is to be at least the percentage stated for the node in table 4, column 4; and
- (iv) the performance indicator mentioned in item 1(d) is to be at least the percentage stated for the node in table 4, column 5; and
- (v) the performance indicator mentioned in item 1(e) is to be at least the percentage stated for the node in table 4, column 6; and
- (vi) the performance indicator mentioned in item 1(f) is to be at least the percentage stated for the node in table 4, column 7; and
- (vii) the performance indicator mentioned in item 1(g) is to be at least the percentage stated for the node in table 4, column 8.

**Table 4**

### 3 Definitions for pt 3

In this part—

**2-times base flow event** means a post-winter flow year in which the days of flow twice base flow are not more than 4 days fewer than the days of flow twice base flow in the year for the pre-development flow pattern.

**2-week lag event** means a first post-winter flow event that starts within 2 weeks of the date the first post-winter flow event starts in the same year for the pre-development flow pattern.

**5-times base flow event** means a post-winter flow year in which the days of flow 5-times base flow are not more than 4 days fewer than the days of flow 5-times base flow in the year for the pre-development flow pattern.

**5-week lag event** means a first post-winter flow event that starts within 5 weeks of the date the first post-winter flow event starts in the same year for the pre-development flow pattern.

**daily flow** means the volume of water that flows past a node in a day.

***days of flow 5-times base flow*** means the number of days in a first post-winter flow event on which the daily flow is at least 5 times the base flow.

***days of flow twice base flow*** means the number of days in a first post-winter flow event on which the daily flow is at least twice the base flow.

***event volume***—

- 1 *Event volume* means the total daily flows for a first post-winter flow event.
- 2 However, if the event volume calculated under paragraph 1 is greater than the volume of the estuary of the Fitzroy River, the event volume is the estuary volume.

***first peak flow***—

- 1 *First peak flow* means the daily flow on the first day in a first post-winter flow event on which the flow reaches a peak.
- 2 However, if the first peak flow calculated under paragraph 1 is greater than the daily flow for a flow with a nominal depth of 3m (a ***3-metre event***), the first peak flow is the daily flow for a 3-metre event.

***first post-winter flow event***—

- 1 *First post-winter flow event*, at a node, means the first flow in a year that—
  - (a) starts between 15 September and 10 April in the year; and
  - (b) either—
    - (i) for node 9A—lasts for 18 days; or
    - (ii) for another node—lasts for 21 days; or
  - (c) the chief executive is satisfied meets the following criteria—
    - (i) for node 0—

- (A) the flow at its start is at least 5000ML a day; and
- (B) the event has an event volume greater than half the volume of the estuary of the Fitzroy River;
- (ii) for another node—
  - (A) the flow, within 6 days after its start, is greater than a flow with a nominal depth of 1.5m; and
  - (B) the first peak in the flow that is greater than a flow with a nominal depth of 1.5m happens within 6 days after the start of the event;
- (iii) if the flow starts in September, the water temperature is at least 24°C;
- (iv) for the duration of the event the flow, at the node, is greater than the base flow for the node mentioned in table 1, column 2.

2 However, a first post-winter flow event does not include a flow that happens in a year in the simulation period for which a flow satisfying the requirements of paragraph 1 did not happen for the pre-development flow pattern.

**peak flow ratio** means the first peak flow for a year expressed as a percentage of the first peak flow for the year for the pre-development flow pattern where the ratio is less than or equal to 1.

**post-winter flow year** means a year in the simulation period in which a first post-winter flow event happens for the pre-development flow pattern.

**volume ratio** means the event volume for a year, expressed as a percentage of the event volume for the year for the pre-development flow pattern where the ratio is less than or equal to 1.

**year** means a period of 12 months beginning on 1 July.

## Part 4 Groundwater objectives

For each node mentioned in table 5, column 1, the drawdown duration for the corresponding specified height in column 2 is not less than the corresponding percentage in column 3.

Table 5

Column 1	Column 2	Column 3
Node	Specified height above June 2007 level (metres)	Percentage
31	2	85
32	2	85
33	3	85
34	0	75

## **Schedule 7      Water allocation security objectives**

sections 21 and 23

### **Part 1                      Supplemented water**

#### **1                      Callide Valley Water Supply Scheme**

- 1 For water allocations in the high A priority group—
  - (a) the annual supplemented water sharing index is to be at least 95%; and
  - (b) the monthly supplemented water sharing index is to be at least 98%.
- 2 For water allocations in the high B priority group—the annual supplemented water sharing index is to be at least 95%.
- 3 For water allocations in the risk priority group—the annual supplemented water sharing index is to be at least 60%.
- 4 For water allocations in the medium priority group—the annual supplemented water sharing index is to be at least 65%.

#### **2                      Dawson Valley Water Supply Scheme**

- 1 For water allocations in the high priority group—
  - (a) the annual supplemented water sharing index is to be at least 95%; and
  - (b) the monthly supplemented water sharing index is to be at least 98%.
- 2 For water allocations in the medium priority group—the monthly supplemented water sharing index is to be at least 82%.

- 
- 3 For water allocations in the medium A priority group—the monthly supplemented water sharing index is to be at least 82%.

**3 Lower Fitzroy Water Supply Scheme and Fitzroy Barrage Water Supply Scheme**

- 1 For water allocations in the high priority group—
  - (a) the annual supplemented water sharing index is to be at least 95%; and
  - (b) the monthly supplemented water sharing index is to be at least 98%.
- 2 For water allocations in the medium priority group—the monthly supplemented water sharing index is to be at least 82%.

**4 Nogoia Mackenzie Water Supply Scheme**

- 1 For water allocations in the high priority group—
  - (a) the annual supplemented water sharing index is to be at least 95%; and
  - (b) the monthly supplemented water sharing index is to be at least 98%.
- 2 For water allocations in the medium priority group—the monthly supplemented water sharing index is to be at least 81%.

**Part 2 Unsupplemented surface water**

For water allocations in a water allocation group mentioned in table 1, column 1, the annual volume probability is to be at least the percentage stated for the group in table 1, column 2.

Table 1

Column 1	Column 2
Water allocation group	Annual volume probability
Class 0A	17%
Class 1A	73%
Class 1B	71%
Class 2A	47%
Class 2B	47%
Class 3A	38%
Class 4C	95%
Class 5A	61%
Class 5B	73%
Class 6C	95%
Class 7D	93%
Class 8A	48%
Class 9A	55%
Class 9B	47%
Class 10A	68%
Class 10B	68%
Class 10C	66%
Class 11A	63%
Class 11B	60%
Class 12A	63%
Class 13A	60%
Class 13C	67%

### Part 3                      Unsupplemented groundwater

For water allocations in a water allocation group mentioned in table 2, column 1, the annual volume probability is to be at least the percentage stated for the group in table 2, column 2.

Table 2

Column 1	Column 2
Water allocation group	Annual volume probability
GWA1A	95%
GWA1B	75%
GWA2A	95%
GWA2B	75%
GWA3A	95%
GWA3B	85%

**Schedule 8 Unallocated water**

section s40 and 47

**Part 1 Strategic reserve for surface water that may be granted—water licence**

Consultation draft

Column 1	Column 2	Column 3
Subcatchment	State purpose nominal entitlement (ML)	Indigenous purpose nominal entitlement (ML)
Isaac Connors	15000	5000

600 to 660	1400	95
750	2375	160
800	2900	201

Consultation draft

## Schedule 11 Water allocation groups to take unsupplemented surface water

sections 90(2) and 96

Column 1	Column 2	Column 3	Column 4
Place	Flow condition	Water allocation group	Number of days
Nogoa River from the upstream limit of Fairbairn Dam at AMTD 737.5km to its junction with Theresa Creek	2592ML/day	Class 0A	Not applicable
Theresa Creek from its junction with Retreat Creek at AMTD 15.0 km to its junction with the Nogoa River	more than 0ML/day	Class 8A	24
Retreat Creek, including anabranches, from its junction with Kettle Creek at AMTD 23.6km to its junction with Theresa Creek			
Comet River, including anabranches, from Lake Brown gauging station AMTD 199.2km to its junction with the Nogoa River	less than 864ML/day	Class 9A	24
	equal to or more than 864ML/day	Class 9B	20

Column 1	Column 2	Column 3	Column 4
Place	Flow condition	Water allocation group	Number of days
Dawson River from its junction with Mimosa Creek at AMTD 133km to its junction with the Mackenzie River, including sections of tributaries where Dawson River flows are accessible	1296ML/day	Class 10A	20
	2592ML/day	Class 10B	19
Dawson River from the end of the supplemented section at AMTD 18.37km to its junction with the Mackenzie River, including sections of tributaries where Dawson River flows are accessible	0 to 25ML/day	Class 10C	Not applicable
Dawson River from Orange Creek Weir at AMTD 270.7km to its junction with Mimosa Creek at AMTD 133km, including sections of tributaries where Dawson River flows are accessible	1296ML/day	Class 11A	20
	2592ML/day	Class 11B	19

Consultation draft

## Schedule 11

Column 1	Column 2	Column 3	Column 4
Place	Flow condition	Water allocation group	Number of days
Dawson River from the upstream limit of Glebe Weir at AMTD 356.5km to Orange Creek Weir at AMTD 270.7km, including sections of tributaries where Dawson River flows are accessible	1296ML/day	Class 12A	20
Dawson River from Utopia Downs Gauging Station at AMTD 453.5km to the upstream limit of Glebe Weir at AMTD 356.5km, including sections of tributaries where Dawson River flows are accessible	up to 1296ML/day	Class 13A	20
	up to 25ML/day	Class 13C	Not applicable

Consultation draft

## Schedule 12 Formula for annual proportional flow deviation

schedule 13, definition *annual proportional flow deviation*

$$APFD = \sum_{j=1}^p \frac{\sqrt{\sum_{i=1}^{12} \left( \frac{c_{ij} - n_{ij}}{\bar{n}_i} \right)^2}}{p}$$

where—

*APFD* means annual proportional flow deviation.

*i* means a particular month.

*j* means a particular year.

*p* means the number of years.

*c<sub>ij</sub>* means the modelled flow for month *i* in year *j*.

*n<sub>ij</sub>* means the modelled natural flow for month *i* in year *j*.

$\bar{n}_i$  means the modelled natural flow for month *i* across *p* years.

## Schedule 13 Dictionary

### section 3

Consultation draft

**2 year daily flow volume**, for a node, means the daily flow, at the node, that has a 50% probability of being reached at least once a year.

**5 year daily flow volume**, for a node, means the daily flow, at the node, that has a 20% probability of being reached at least once a year.

**20 year daily flow volume**, for a node, means the daily flow, at the node, that has a 5% probability of being reached at least once a year.

**4% daily exceedance duration flow**, for a node, means the daily flow that is equalled or exceeded on 4% of days in the simulation period.

**10% daily exceedance duration flow**, for a node, means the daily flow that is equalled or exceeded on 10% of days in the simulation period.

**30% unsupplemented water sharing index**, for a group of water allocations, means the total volume of water simulated to have been taken annually under the allocations in at least 30% of years in the simulation period, if the allocations were in existence for the whole of the simulation period, expressed as a percentage of the total of the nominal volumes for the allocations in the group for the allocations.

**50% unsupplemented water sharing index**, for a group of water allocations, means the total volume of water simulated to have been taken annually under the allocations in at least 50% of years in the simulation period, if the allocations were in existence for the whole of the simulation period, expressed as a percentage of the total of the nominal volumes for the allocations in the group for the allocations.

**70% unsupplemented water sharing index**, for a group of water allocations, means the total volume of water simulated

to have been taken annually under the allocations in at least 70% of years in the simulation period, if the allocations were in existence for the whole of the simulation period, expressed as a percentage of the total of the nominal volumes for the allocations in the group for the allocations.

**2007 authorisation**, for chapter 5, part 3, division 4, see section 138.

**2007 authorisation volume**, for chapter 5, part 3, division 4, see section 138.

**2010 moratorium publication day** means the day the December 2010 moratorium was published under section 26(1) of the Act.

*Editor's note—*

A copy of the moratorium is available on the department's website at <[www.derm.qld.gov.au](http://www.derm.qld.gov.au)>.

Note—'2010 moratorium publication day' is a placeholder definition for the purposes of consultation. The Dept proposes to publish a moratorium in December 2010. In the final plan, that date will be known and will replace the instances of this term throughout the plan.

**accounted use**, for chapter 5, part 3, division 4, see section 138.

**adopted middle thread distance** means the distance in kilometres, measured along the middle of a watercourse, that a specific point in the watercourse is, at the commencement of this plan, from—

- (a) the watercourse's mouth; or
- (b) if the watercourse is not a main watercourse—the watercourse's confluence with its main watercourse.

**amended water licence—**

- (a) for chapter 5, part 2, division 8, subdivision 2, see section 101; or
- (b) for chapter 5, part 3, division 2, subdivision 2, see section 118.

**AMTD** means the adopted middle thread distance.

**annual adjusted use volume**, for chapter 5, part 3, division 4, see section 138.

**annual entitlement** see the *Water Regulation 2002*, section 67.

**annual flow volume**, for a node, means the total volume of flow, at the node, in a period of 12 months starting on 1 July.

**annual proportional flow deviation**, for a node, means the statistical measure of changes at the node to flow season and volume in the simulation period calculated using the formula in schedule 12.

**annual supplemented water sharing index**, for water allocations to take supplemented water in a particular priority group, means the percentage of years in the simulation period in which the allocations are fully supplied.

**annual volume probability**, for a water allocation group, means the percentage of years in the simulation period in which the volume of water that may be taken by the group is at least the total of the nominal volumes for the allocations in the group.

**annual volumetric limit**, for an interim water allocation or water allocation, means the maximum volume of water that may be taken under the allocation in a water year.

**authorisation** means a licence, permit, interim water allocation or other authority to take water given under the Act or the repealed Act, other than a permit for stock or domestic purposes.

**base flow**, for a node, means the flow stated for the node in schedule 6, part 1, table 1, column 2.

**baseflow** means the part of streamflow derived from the natural discharge of groundwater into a watercourse, lake or spring.

**Braeside borefield** means a bore field of production bores near Nebo that takes groundwater from the Denison Creek alluvium in the Isaac Connors Alluvium groundwater sub-area.

***Callide groundwater notification area*** means the area identified as the Callide groundwater notification area shown in schedule 3.

***Callide Valley groundwater computer program*** means the department's computer program and associated data files, and statistical and data processing programs, that simulate groundwater levels, groundwater demand, recharge and groundwater flows in parts of the Callide Groundwater Unit 1.

***Callide Valley Water Supply Scheme*** means the scheme for the supply of water under the interim resource operations licence for the Callide Valley Water Supply Scheme.

***carry over***, for chapter 5, part 3, division 4, see section 138.

***converting authorisation***, for chapter 5, part 3, division 4, see section 138.

***daily flow***, for a node, means the volume of water, expressed in megalitres, that flows past the node in a day.

***daily volumetric limit***, for a water allocation, means the maximum volume of water that may be taken under the water allocation in a day.

***Dawson Valley Water Supply Scheme*** is the scheme for the supply of water under the resource operations licence for the Dawson Valley Water Supply Scheme.

***deemed use***, for chapter 5, part 3, division 4, see section 138.

***discharge***, for a flow at a point in a watercourse, means the rate at which water passes the point, measured in cubic metres a second or megalitres a day.

***drawdown duration*** means the percentage of days in the simulation period that the water level is above a specified height above the June 2007 level.

***ecological assets*** include a species, a group of species, a biological function, an ecosystem and a place of natural value.

***existing groundwater works*** means—

- (a) works that are prescribed existing groundwater works; and

- (b) works, other than prescribed existing groundwater works, that were in existence immediately before the commencement of this plan.

***existing overland flow works***—

- (a) means works that allow the taking of overland flow water and—
  - (i) for an owner of land—were in existence on 13 September 2001; or
  - (ii) for a lessee under a mining lease—were in existence before the commencement of this plan; and
- (b) includes works that—
  - (i) are a reconfiguration of existing overland flow works (the ***original works***); and
  - (ii) do not increase the average annual volume of water taken above the average annual volume taken using the original works.

***Fitzroy Barrage Water Supply Scheme*** is the scheme for the supply of water under the resource operations licence for the Fitzroy Barrage Water Supply Scheme.

***flow regime*** means the entire range of flows at a point in a watercourse including variations in the watercourse height, discharge, seasonality and annual variability.

***forward draw***, for chapter 5, part 3, division 4, see section 138.

***groundwater*** means underground water that is subartesian water not connected to artesian water.

***groundwater management area*** means the groundwater management area under section 6.

***groundwater sub-area*** means a groundwater sub-area under section 7.

***groundwater unit*** means a groundwater unit under section 7.

***HOU consideration period***, for chapter 5, part 3, division 4, see section 138.

**hydraulic habitat requirements**, of an ecological asset, are the hydraulic or physical attributes of the flow regime or groundwater that are—

- (a) required for a particular biological process or response to happen in relation to the asset; or
- (b) necessary to maintain the long-term biological integrity of the asset.

**hyporheic zone** means the zone where an exchange between surface water and groundwater happens.

**Indigenous purpose** means a use for the purpose of helping an Indigenous community achieve its economic and social aspirations.

**IQQM computer program** means the department's Integrated Quantity and Quality Modelling computer program, and associated statistical analysis and reporting programs, that simulate daily stream flows, flow management, storages, releases, instream infrastructure, water diversions, water demands and other hydrologic events in the plan area.

**Isaac Connors groundwater notification area** means the area identified as the Isaac Connors groundwater notification area shown in schedule 3.

**June 2007 level** means the actual water level on 30 June 2007.

**Lower Fitzroy Water Supply Scheme** is the scheme for the supply of water under the resource operations licence for the Lower Fitzroy Water Supply Scheme.

**mean annual flow**, for a node, means the total volume of flow, at the node, in the simulation period divided by the number of years in the simulation period.

**mean wet season flow**, for a node, means the total volume of flow during the months of January, February, March and April in the simulation period divided by the number of years in the simulation period.

**median annual flow ratio**, for a node, means the ratio of the annual flow volume in the simulation period to the corresponding annual flow volume for the pre-development

flow pattern that is equalled or exceeded in 50% of years in the simulation period.

**mine dewatering** means the removal of groundwater that is necessary to ensure a safe and efficient mine working environment for an authorised activity for a mining tenement under the *Mineral Resources Act 1989*.

*Examples—*

- the removal of groundwater that has accumulated in mine workings
- the extraction of groundwater from bores surrounding the mine workings to lower the water table or hydraulic pressure

**mining lease** see the *Mineral Resources Act 1989*, schedule.

**modern coastal deposits** means quaternary colluvial and alluvial sediments in close proximity to the coast in the Fitzroy groundwater management area.

**monthly supplemented water sharing index**, for water allocations to take supplemented surface water in a particular priority group, means the percentage of months in the simulation period in which the allocations are fully supplied.

**node** see section 9.

**Nogoa Mackenzie Water Supply Scheme** is the scheme for the supply of water under the resource operations licence for the Nogoa Mackenzie Water Supply Scheme.

**nominal entitlement** see the *Water Regulation 2002*, section 65.

**plan area** see section 4.

**pre-2007 contributing authorisation**, for chapter 5, part 3, division 4, see section 138.

**pre-development flow pattern** means the pattern of water flows, during the simulation period, decided by the chief executive using the IQQM computer program as if—

- (a) there were no dams or other water infrastructure in the plan area; and
- (b) no water was taken under authorisations in the plan area.

**prescribed authorisation**, for chapter 5, part 3, division 4, see section 138.

**prescribed existing groundwater works**, for chapter 5, part 3, division 2, subdivision 3, see section 122.

**previous authorisation**, for chapter 5, part 3, division 3, see section 127.

**project of State significance** means a project declared under the *State Development and Public Works Organisation Act 1971*, section 26 to be a significant project.

**quaternary alluvium**, means the quaternary age alluvial deposits of sand, gravel, silt and clay.

**refugia** means the habitat required by a species during a time of stress, for example, drought.

**relevant groundwater-dependent ecosystem** means a groundwater-dependent ecosystem that is a riparian vegetation ecosystem or terrestrial vegetation ecosystem.

**riparian vegetation ecosystem** means a vegetation ecosystem that includes groundwater-dependent vegetation growing on, or immediately adjacent to, the banks of a lagoon or stream in the plan area.

**seasonality**, in relation to the flow in a watercourse, means the time of year when the flow happens.

**simulated mean annual diversion**, for an authorisation or group of authorisations, means the total volume of water simulated to have been taken under the authorisations, if the authorisations were in existence for the whole of the simulation period, divided by the number of years in the simulation period.

**simulation period** means the period from 1 January 1900 to 31 December 2007.

**State purpose** means—

- (a) a project of State significance; or
- (b) a project of regional significance; or
- (c) town water supply purposes; or

- (d) use by Indigenous peoples for non-commercial purposes, including cultural and traditional purposes.

**subcatchment area** see section 5.

**supplemented water** means water supplied under an interim resource operations licence, resource operations licence or other authority to operate water infrastructure.

**surface water** see section 10(1).

**terrestrial vegetation ecosystem** means a vegetation ecosystem, other than a riparian vegetation ecosystem.

**this plan** means this water resource plan.

**traditional owners**, of an area, means the Aboriginal people who identify as descendants of the original inhabitants of the area.

**unallocated water** means water available for allocation in the plan area.

**unsupplemented water** means water that is not supplemented water.

**volume density**, for a locality in a part of the groundwater management area, means the total annual volumetric limits for all the water allocations in the locality divided by the area of the locality.

**water accounts**, for chapter 5, part 3, division 4, see section 138.

**water bore** means a subartesian bore.

**water flow season** means any of the following periods in a year—

- (a) the period from 1 January to 30 April (**January–April water flow season**);
- (b) the period from 1 May to 31 August (**May–August water flow season**);
- (c) the period from 1 September to 31 December (**September–December water flow season**).

***waterhole*** means a part of a watercourse that contains water after the watercourse ceases to flow, other than a part of a watercourse that is within the storage area of a dam on the watercourse.

***water year***, for chapter 5, part 3, division 4, see section 138.

***works that allow the taking of overland flow water*** include—

- (a) storages, sumps, drains, embankments, channels and pumps for taking, or that can be used for taking, overland flow water; and
- (b) storages that are connected to the works mentioned in paragraph (a); and
- (c) works that make, or that can be used to make, the original connection between the storages mentioned in paragraph (b) and the works mentioned in paragraph (a).

ENDNOTES

# 1. Introduction

The *Water Supply (Safety and Reliability) Act 2008* (the Act) commenced on 1 July 2008. The purpose of the Act is to provide for the safety and reliability of water supply throughout Queensland.

The Act also introduces new provisions relating to the management of drinking water quality, aimed at protecting public health. This outcome is achieved primarily through the regulatory framework for drinking water quality which requires drinking water service providers to:

- undertake monitoring and reporting on drinking water quality
- have an approved drinking water quality management plan (the plan) in place.

The Act can be accessed online at <[www.legislation.qld.gov.au](http://www.legislation.qld.gov.au)>.

## 1.1 Scope of the *Water Supply (Safety and Reliability) Act 2008*

### 1.1.1 Administration of the Act

The Act is administered by the chief executive (Director-General) of the Department of Environment and Resource Management (the department). The chief executive of the department is the regulator under the Act. The chief executive of the department, as the regulator, has delegated certain powers under the Act to officers of the Office of the Water Supply Regulator.

### 1.1.2 Definition of drinking water

The Act defines drinking water to mean water for human consumption, intended primarily as water for drinking, whether or not the water is used for other purposes. Drinking water does not include:

- (a) water that is food as defined under the *Food Act 2006*<sup>1</sup>
- or
- (b) water taken or supplied for domestic purposes under the *Water Act*<sup>2</sup>.

### 1.1.3 Definition of a drinking water service provider

The Act defines a drinking water service provider as a water service provider for a drinking water service. A water service provider means a person registered under Chapter 2, part 3 of the Act as a service provider for a water service.

A water service does not include a service supplied by infrastructure, if:

- (a) the infrastructure is used solely for mining purposes
- or
- (b) the service is used only by:
  - (i) the owner of the infrastructure or the owner's guests or employees including, for example, guests at a resort
  - or
  - (ii) if the owner of the infrastructure is a body corporate for a community titles scheme under the *Body Corporate and Community Management Act 1997*—the occupants of lots in the scheme.

---

<sup>1</sup>This is water sold for human consumption (for example, bottled water) or is used by a food business that involves the handling of food intended for sale or the sale of food. It also includes water carried in bulk in a vehicle and intended for human consumption, regardless of the source of water.

<sup>2</sup>In the *Water Act 2000*, the term 'domestic purposes' includes irrigating a garden not exceeding .25 ha, being a garden cultivated for domestic use and not for the sale, barter or exchange of goods produced in the garden. Domestic purposes are sometimes referred to as 'stock and domestic' water.

### 1.1.4 Definition of a drinking water service

A drinking water service means a water service that is:

- (a) the treatment, transmission or reticulation of water for supply as drinking water; or
- (b) water collection in a water storage, if the water in the storage:
  - (i) includes recycled water
  - and
  - (ii) is used to augment a drinking water supply.

## 1.2 Aim of this guideline

This guideline has been developed to provide information to drinking water service providers (providers) about preparing the plan. Section 95(3) of the Act states that the plan must be prepared in accordance with this guideline.

Information contained in this guideline includes details on:

- requirements of the Act and related criteria
- matters considered by the regulator in assessing the plan and making a decision about the plan
- operating under the plan
- amending the plan
- adopting best practice recommendations.

It is the responsibility of the provider to meet the requirements of the Act and to provide the necessary information to fulfil these requirements. This will ensure that all relevant information needed by the regulator to make a decision about the plan is available.

This guideline also contains a series of best practice recommendations in recognition of current practices that promote the safe supply of drinking water within the industry. These recommendations are primarily based on the Australian Drinking Water Guidelines (ADWG). Providers are encouraged to consider, and where possible or practical adopt, these recommendations in the plan to demonstrate their continued commitment to achieving industry best practice.

It is anticipated that this guideline will be reviewed on a regular basis.

This guideline can be accessed online at <[www.derm.qld.gov.au](http://www.derm.qld.gov.au)>.

## 1.3 Relationships to other guidelines

### 1.3.1 Other regulatory guidelines

This guideline is part of a suite of guidelines prepared to assist water service providers in understanding the regulatory requirements that the Act places on them. In addition to this guideline, other water related regulatory guidelines in this suite include the:

- Drinking Water Quality Management Plan Auditing and Review Guideline<sup>3</sup>
- Drinking Water Quality Management Plan Annual Reporting Guideline<sup>4</sup>
- Water Quality and Reporting Guideline for a Drinking Water Service
- Water Quality Guidelines for Recycled Water Schemes
- Recycled Water Management Plan and Validation Guidelines

---

<sup>3</sup> The Drinking Water Quality Management Plan Auditing and Review Guideline is being developed and will be made available when approved.

<sup>4</sup> The Drinking Water Quality Management Plan Annual Reporting Guideline is being developed and will be made available when approved.

- Recycled Water Management Plan Exemption Guidelines
- Guidelines for the Preparation of a System Leakage Management Plan
- Guidelines for Granting Exemptions for a System Leakage Management Plan
- Guidelines for Preparing Strategic Asset Management Plans
- Guidelines for Preparing Customer Service Standards
- Guidelines for Granting Exemptions for: Strategic Asset Management Plans, Customer Service Standards and Annual Reports
- Guidelines for the Review and Regular Audit of Strategic Asset Management Plans
- Annual Reporting of Strategic Asset Management Plan and Customer Service Standards Guidelines for Service Providers
- Guidelines for the Preparation of a Drought Management Plan.

## 1.4 Relationship to other legislation and regulations

### 1.4.1 Public health

At the same time the Act was established, amendments were made to the *Public Health Act 2005* and the Public Health Regulation 2005 to include provisions relating to drinking water quality.

As the administrator of the Public Health Act and the Public Health Regulation, Queensland Health has:

- set specific standards for drinking water quality in the Regulation
- the power to respond when drinking water supplied by a provider may present a risk to public health or be considered unsafe<sup>5</sup>.

Under section 57E of the Public Health Act, it is an offence for a provider to supply drinking water that the provider knows, or reasonably ought to know, is unsafe. The maximum penalty for the offence is 3000 penalty units or two years imprisonment.

Section 57C of the Public Health Act states that ‘drinking water is unsafe at a particular time if it would be likely to cause physical harm to a person who might later consume it, assuming nothing happened to it after that particular time and before being consumed by the person that would prevent its being used for its intended use’.

### 1.4.2 Other legislation and regulations

The operations of a water service or a drinking water service (the service) will also be covered under other state and Commonwealth legislation, such as the *Workplace Health and Safety Act 1995*, *Plumbing and Drainage Act 2002*, *Sustainable Planning Act 2009*, *Water Fluoridation Act 2008*, *Environmental Protection Act 1994*, *South-East Queensland Water (Distribution and Retail Restructuring) Act 2009*, *Water Act 2000* and the *Trade Practices Act 1974*.

The requirements of the *Water Supply (Safety and Reliability) Act 2008* do not negate the requirements of other legislation unless where expressly stated. It is the responsibility of the provider to determine and ensure compliance with relevant legislative obligations. The provider is also responsible for obtaining any necessary approvals under the other Acts to ensure the continued operation of the service. The plan only relates to matters under the *Water Supply (Safety and Reliability) Act 2008*.

---

<sup>5</sup> For example, Queensland Health can require action to be taken to protect public health by the issue of a public health order or an improvement notice to a provider.

## **1.5 Other resource material**

It is recognised that a variety of existing resources are used by industry to ensure the safe supply of drinking water. While these resources hold valuable information on supplying safe drinking water, providers may also find them useful when preparing the plan. Refer to the Preparing a Drinking Water Quality Management Plan: Supporting Information (supporting information) document which accompanies this guideline for further information relating to these resources.

## 2. Drinking water quality management plan

### 2.1 The drinking water quality management plan

The drinking water quality management plan (the plan) is about the storage, treatment, transmission or reticulation of water for drinking by a provider. Under section 95 of the Act, the plan must be prepared by a provider and must:

- (i) state the registered services to which the plan applies
- (ii) include details of the infrastructure for providing the services
- (iii) identify the hazards and hazardous events the drinking water service provider considers may affect the quality of water to which the services relate
- (iv) include an assessment of the risks posed by the hazards and hazardous events
- (v) demonstrate how the drinking water service provider intends to manage the risks posed by the hazards and hazardous events
- (vi) include details of the operational and verification monitoring programs under the plan, including the parameters to be used for indicating compliance with the plan and the water quality criteria for drinking water.

No exemptions will be granted by the regulator from preparing the plan.

Refer to Chapter 3 of this guideline for detailed information on the matters to be considered and/or included in the plan.

### 2.2 Purpose of the plan

In accordance with section 94 of the Act, the purpose of the plan is to protect public health through the identification and minimisation of any public health related risks associated with drinking water.

The drinking water quality management provisions in Queensland follow a risk management approach and it is intended that the plan be a documented, risk-based system for managing the supply of drinking water. It is also intended that the plan be a living document that reflects the requirements of the provider and be actioned through the provider's day to day activities now and in the future. To ensure that this is achieved, senior management should be actively involved in the development and implementation of the plan and encourage an organisational philosophy and culture that supports drinking water quality. The plan should be viewed by the provider as a means of achieving drinking water quality outcomes (in the short and long-term) and demonstrating that drinking water quality management measures are in place.

### 2.3 Requirement to prepare the plan

Section 95(1) of the Act states that each provider must prepare the plan for the service and apply to the regulator for approval of the plan (this includes providers that supply bulk water, manufactured water and distributor-retailer services). While a service may comprise of one or more discrete drinking water schemes<sup>6</sup> (scheme(s)), all the schemes must be covered by the plan. Non-potable water supply schemes are not to be included in the plan.

The costs of preparing and maintaining the plan must be borne by the provider.

### 2.4 Timeframes for preparing the plan

An approved plan is not required while transitional periods are in place. Table 1 outlines the statutory deadlines for requiring an approved plan. Providers must submit the plan in advance of the dates to allow sufficient<sup>7</sup> time for the regulator to consider and make a decision about the plan.

---

<sup>6</sup> For a definition of a drinking water scheme, see the glossary of this guideline, or the Water Quality and Reporting Guideline for a Drinking Water Service.

<sup>7</sup> Refer to section 4.2.3 of this guideline for timeframes for decisions.

**Table 1: Statutory deadlines for requiring an approved plan**

Service provider <sup>8</sup>	Timeframes
Large	Must have an approved plan in place by 1 July 2011
Medium	Must have an approved plan in place by 1 July 2012
Small	Must have an approved plan in place by 1 July 2013
Providers that store or treat source water containing recycled water <sup>9</sup> intended to augment a drinking water supply	Must have an approved plan before recycled water used to augment a drinking water supply can be added to the source water
New drinking water service provider	Must have an approved plan one year after the day of becoming a provider

Under section 629 of the Act, the regulator may require the plan to be prepared at an earlier time, if the regulator is satisfied or reasonably believes that the continued operation of the service may have an adverse effect on public health.

## 2.5 Multiple providers involved in preparing the plans

In the majority of cases, the service serving one or more communities would be owned and operated by a single provider. However, there are situations where the supply of drinking water to a community may involve multiple providers. For example, where:

- a provider supplies bulk treated water to another provider or providers, who are responsible for treatment, transmission and reticulation to the community served (refer to figure 1)
- a provider supplies bulk treated water to a second provider who is then responsible for the transmission of the water to a third provider (or group of providers). This third provider (or group of providers) is responsible for the reticulation to the community served (refer to figure 2)
- a recycled water provider supplies recycled water for the purposes of augmenting drinking water to another provider, who is then responsible for treatment, transmission and reticulation of water to the community served (refer to figure 3).

The Act requires each provider to prepare the plan relating to the service. Where there are multiple providers involved in the supply of drinking water to a community or communities, each provider must prepare the plan that relates to their respective service. As shown in the diagram below, while each plan is linked to the other as a result of the drinking water supply chain, a provider is only responsible for the preparation of the plan that relates to their service.

**Figure 1: Provider supplying bulk treated water to another provider for the treatment, transmission and reticulation**

<sup>8</sup> For the definition of large, medium and small service provider, see the glossary of this guideline, or schedule 3 of the Act.

<sup>9</sup> In the context of this guideline, recycled water refers to recycled water that is used to augment a drinking water supply. This is commonly known as purified recycled water (PRW).

**Figure 2: Provider supplying bulk treated water to other providers for treatment, transmission or reticulation**

**Figure 3: Bulk water provider receives recycled water into their water storage for the purposes of augmenting a drinking water supply**

The linkages between these plans are critical to the protection of public health as the supply of water from the catchment to the consumer is seen as a continuum. All multiple providers involved in the supply of drinking water play a key role in protecting public health. Therefore, it is vital that each multiple provider understands:

- their role and responsibilities in the supply of drinking water
- how the provider’s actions impact another provider’s infrastructure or quality of water received or supplied
- their role in managing the situation when the water quality is compromised.

The relationship between multiple providers is important particularly those immediately upstream or downstream to their service. Each provider should consider available and relevant information to ensure hazards and risks are effectively managed from catchment to consumer.

In preparing the plan, the provider should consider, where relevant:

- existing agreements and arrangements between providers for the supply of water
- communication protocols
- emergency response plans, protocols and procedures
- general reporting (including incident reporting), management protocols and procedures
- water quality monitoring programs
- other related documents, actions or matters.

Chapter 3 of this guideline outlines specific criteria that relate to multiple providers. It is recognised that due to commercial-in-confidence issues, some aspects of the information relating to the specific criteria (that is, catchment characterisation, hazard identification, risk assessment) may not be readily available between providers, however, providers should endeavour to use all their available knowledge and information to address the criteria in the plan.

The applicability of some of the criteria may vary across multiple providers based on the provider’s service. For example, catchment characterisation is not required by a provider that only undertakes transmission or distribution services, however, the provider should be aware of the quality of water entering or leaving their service, and any hazards that may impact on their service from an upstream provider. Similarly, a provider that undertakes distribution is not required to provide information relating to treatment and disinfection processes in the plan unless it forms part of their service.

### **2.5.1 Augmenting a drinking water supply with recycled water**

When a drinking water service is augmented with recycled water, the Act requires both a drinking water quality management plan and a recycled water management plan to be approved before recycled water is introduced into the drinking water supply. The drinking water quality management plan for the receiving water storage must be approved by the regulator before the recycled water management plan can be approved.

The provider must adequately consider the hazards and risks associated with the augmentation of drinking water with recycled water, and any other existing plans relevant to the supply, when preparing the drinking water quality management plan for the receiving water storage. The drinking water quality management plan(s) and the recycled water management plan must collectively demonstrate the management of risks from the catchment to the consumer to protect public health.

## 3. Preparing the drinking water quality management plan

This chapter outlines information relevant to a provider when preparing the plan, including:

- an overview on how to prepare the plan
- incorporating existing plans and procedures
- the specific criteria that the provider must meet in accordance with the Act
- best practice recommendations.

### 3.1 Overview on how to prepare the plan

Section 95(3) of the Act states that the plan must be prepared in accordance with this guideline. It should be noted that:

- each provider must submit the plan for the service that addresses the legislative requirements. The plan may comprise of:
  - a number of sub-parts to address each scheme associated with the service
  - a collection of existing documents including
    - supporting documentation such as other existing plans (for example, Hazard Analysis and Critical Control Point (HACCP) and ADWG
    - referenced documents and procedures
    - any additional information.
- the detail and complexity of the plan or sub-parts of the plan may vary due to the differences in scheme complexity, size and risks. Overall the level of detail in the plan must be sufficient to support the requirements of the Act aimed to protect public health
- while the plan may be structured in various ways, the criteria outlined in this guideline must be addressed. The provider must demonstrate how they comply with each criteria, rather than simply stating that they do comply
- sufficient supporting information is required to demonstrate how the criteria have been met. However, routine operational and maintenance procedures may simply be referenced<sup>10</sup> in the plan (for example, calibration of testing equipment manual or mains breaks repairs procedures). In considering the plan, the regulator may request this documentation if required (refer to guideline section 4.2.2)
- the criteria are presented in this guideline to align with the requirements of the Act. A provider may choose to address all related criteria collectively and present the information as a component in the plan. For example, all criteria relating to stakeholders or multiple providers may be addressed in a stakeholder or multiple provider section within the plan
- multiple providers involved in the supply of drinking water have an obligation to be aware of the impacts the service may have on an upstream or downstream service and vice versa. Where information on an upstream or downstream service is sought, the provider must, to the best of their ability and knowledge, provide this information to address the relevant criteria
- where further information is required to meet the legislative requirements which was not available at the time of submission of the plan, or additional risk management measures are required, this information should be identified and documented in a separate part of the plan (refer to guideline section 3.9.4).

---

<sup>10</sup> This existing documentation should clearly indicate where the relevant information can be found, to which criteria it applies and to which scheme it relates.

## 3.2 Incorporating existing plans and procedures

A provider may have existing plans or documents that meet all or part of the requirements of the Act, such as:

- risk assessments
- operation and maintenance manuals
- corporate procedures and forms
- other regulatory management plans (for example, strategic asset management plans).

Where a provider submits existing documentation to meet the requirements of the Act, the provider should clearly indicate where the relevant information can be found, to which criteria it applies and to which scheme it relates. The provider must also ensure that existing plans or documents that are being used are current and relevant to the criteria.

## 3.3 Use of risk management methodologies

Risk management focuses on reducing the likelihood of hazards and hazardous events occurring and proactively managing incidents and emergency responses. Risk management is gaining importance within the water industry. There are a range of existing risk identification and management methodologies that could be used to form the basis of the plan such as ADWG, HACCP, ISO 22000 or AS/NZS ISO 31000:2009.

Any risk management methodology can be used for the plan as long as it meets the legislative requirements of the Act. The methodology must be identified in the plan and consistently applied within each scheme. Table 2 provides an overview of where existing risk management methodologies may be used to address the legislative requirements of the Act. In the plan, a provider can, where applicable, use information from any existing risk management methodologies, they may have in place such as ADWG, HACCP or AS/NZ ISO 31000:2009 to satisfy the legislative requirements of the Act. However, it is important to recognise that these risk management methodologies do not address all the requirements. Therefore it is the provider's responsibility to submit any additional information to meet these requirements. For example, if a provider has a HACCP framework in place for managing their drinking water supply, they can submit this information as part of the plan. The provider must submit the additional information in the plan that may not be part of HACCP (for example, registered service details and information gathering for water quality and catchment characteristics) to fully comply with the legislative requirements of the Act.

### 3.3.1 Applying risk management methodologies

It is important to recognise each risk management methodology uses different terminology. This guideline generally uses the terms from the ADWG. As such, the terminology used in this guideline is different to that used in HACCP or AS/NZ ISO 31000:2009, but may have the same meaning or intent as the Act requirements. Where this is the case, the HACCP or AS/NZ ISO 31000:2009 terminology can be used in the plan. For example, preventive measure in the ADWG has the same meaning as a control measure in HACCP and can be referenced as a control measure in the plan. It is preferable that terminology included as part of the plan, where different to that adopted or referenced in this guideline, is described.

**Table 2: Act requirements compared to ADWG, HACCP and AS/NZS ISO 31000:2009 components**

Requirements under the Act	Reference in this guideline	Related ADWG element	Related HACCP task	Related AS/NZS ISO 31000:2009 component
Registered service details				
Section 95(3)(b)(i): state the registered services to which the plan applies	3.5 Registered service details			Establish the context
Details of infrastructure for providing the service				
Section 95(3)(b)(ii):	3.6 Details of	2.1 Water supply	Task 4: Construct	Establish the context

Requirements under the Act	Reference in this guideline	Related ADWG element	Related HACCP task	Related AS/NZS ISO 31000:2009 component
include details of the infrastructure for providing the services	infrastructure for providing the service	system analysis (construct a flow diagram, document key characteristics)	flow diagram	
Identify hazards and hazardous events				
Section 95(3)(b)(iii): identify the hazards and hazardous events the drinking water service provider considers may affect the quality of water to which the services relate	3.7.1 Information gathering—water quality and catchment characteristics	2.2 Assessment of water quality data (assess historical water quality data, exceedences and trend analysis)		Risk assessment (analysis and evaluation)
		2.1 Water supply (catchment to consumer)		
	3.7.2 Hazard identification	2.1 Water supply system analysis (assemble a team) 2.3 Hazard identification and risk assessment (define methodology, identify and document hazards)	Task 1: Assemble HACCP team Task 6: List all potential hazards, conduct hazard analysis	Develop risk criteria Risk assessment: (identification)
Assessment of risks				
Section 95(3)(b)(iv): include an assessment of the risks posed by the hazards and hazardous events	3.8 Assessment of risks	2.3 Hazard identification and risk assessment (evaluate hazards and estimate the risk levels)	Task 6: consider methods to control identified hazards	Risk treatment
Managing risks				
Section 95(3)(b)(v): demonstrate how the drinking water service provider intends to manage the risks posed by the hazards and hazardous events	3.9.1 Risk management measures	3.1 Preventive measures and multiple barriers (identify measures and where improvements are necessary) 7.1 Employee awareness and training (communications mechanisms, qualifications and training needs)	Task 6: Identify control measures Task 7: Determine critical control points Task 8: Establish critical limits for each Critical Control Point (CCP) Training requirement	Preparing and identifying risk treatment plans
	3.9.2 Operation and maintenance procedures	4.1 Operational procedures (identify and document) 4.4 Equipment calibration and maintenance	Task 12: Work procedures should be developed for each CCP	
	3.9.3 Management of incidents and	4.3 Corrective actions (document actions for control excursions and	Task 10: Establish corrective actions	Recording the risk management process

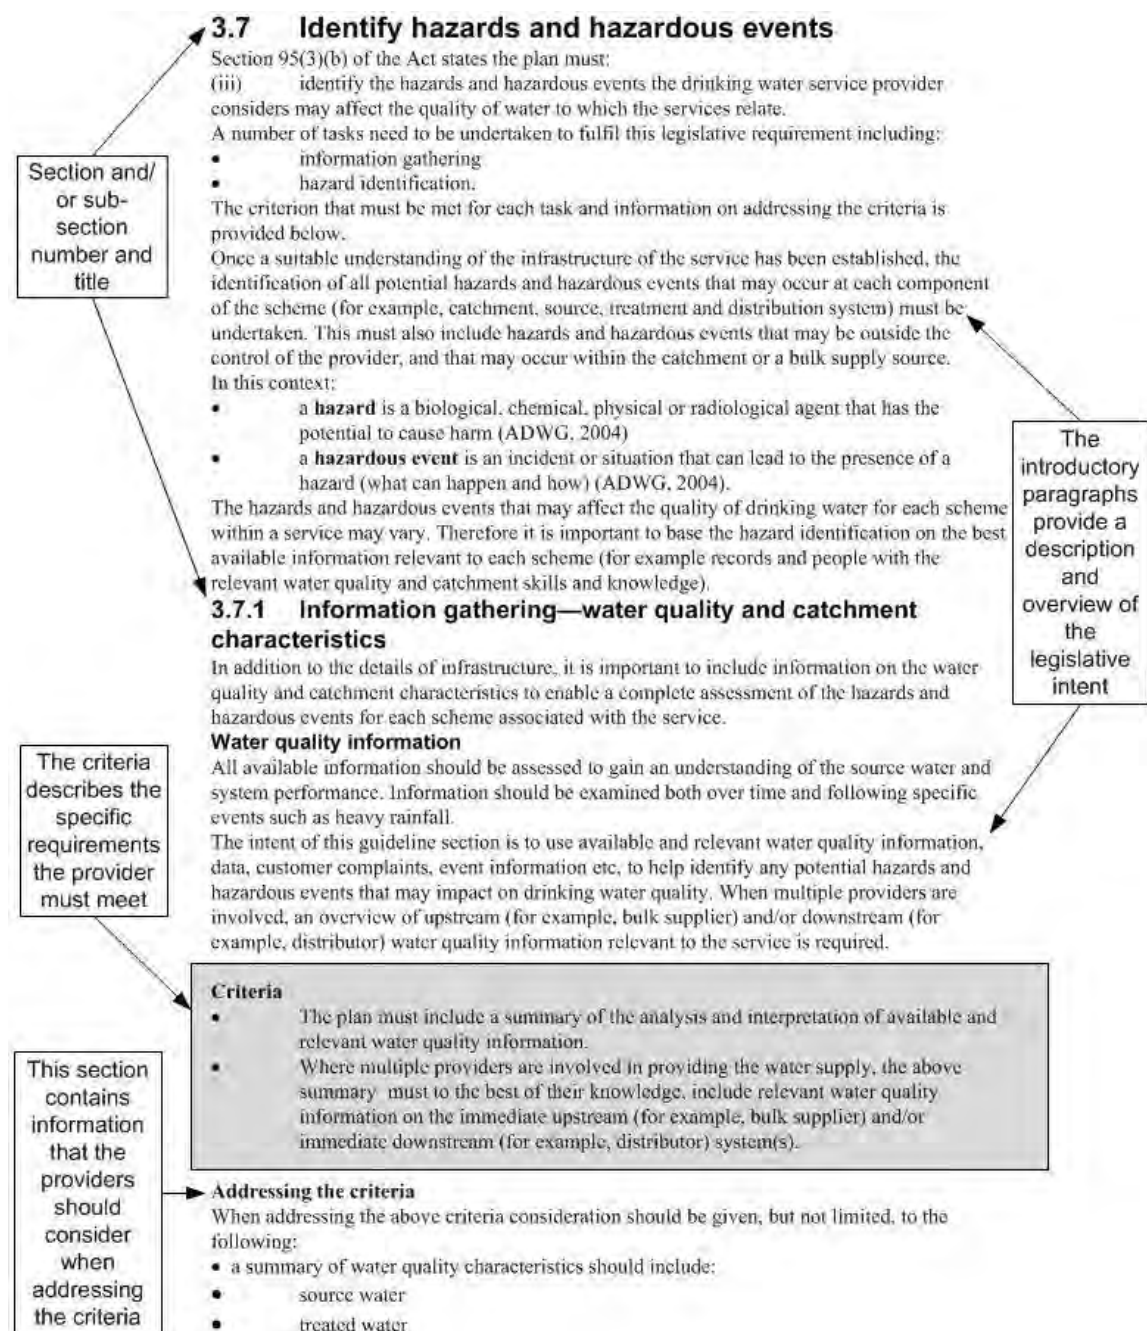

Requirements under the Act	Reference in this guideline	Related ADWG element	Related HACCP task	Related AS/NZS ISO 31000:2009 component
	emergencies	communications systems) 5.4 Corrective actions (document actions for non-conformance)		
	3.9.4 Risk management improvement program	6.1 Communication 6.2 Incident and emergency response 10.2 Reporting protocols 12.2 Drinking water quality management improvement plan	Task 10: Establish corrective actions	Recording the risk management process
	3.9.5 Service wide support—information management	5.3 Short-term evaluation of results 10.1 Management of documentation and records	Task 12: Establish documentation and record keeping	
Operational and verification monitoring programs				
Section 95(3)(b)(vi): include details of the operational and verification monitoring programs under the plan including the parameters to be used for indicating compliance with the plan and the water quality criteria for drinking water	3.10 Operational and verification monitoring programs	3.2 Critical control points 4.2 Operational monitoring (document protocols, set criteria) 5.1 Drinking water quality monitoring 11.1 Long-term evaluation of results	Task 9 Establish a monitoring system for each CCP Task 11 Establish verification and auditing—establish procedures for verification, confirm efficacy of all elements of HACCP system	Monitoring (and review)

### 3.4 Using guideline sections 3.5 to 3.11

Guideline sections 3.5 to 3.10 are based on the legislative requirements under section 95(3) of the Act and follow a standard format, including:

- a section or sub-section number and title
- introductory paragraphs
- criteria—the criteria describe the specific requirements the provider must meet. These requirements are mandatory as they are legislative requirements under the Act and use the word ‘must’. Information required as a ‘must’ is considered the minimum amount of information needed to address the criteria
- addressing the criteria—contains information that the provider should consider when addressing the criteria. It is not intended to be a definitive list and it is the responsibility of the provider to ensure that sufficient, relevant information is provided to demonstrate that they have met the criteria to allow the regulator to make a decision about the plan.

Section 3.11 of this guideline also outlines a number of best practice recommendations. Based on the ADWG, these recommendations reflect current practices within the industry to promote the safe supply of drinking water. There is no requirement under the Act for these recommendations to be incorporated and they will not be assessed by the regulator in making a decision about the plan. Consequently, they do not have any criteria listed. However, the consideration and inclusion of these recommendations in the plan is encouraged, to demonstrate the provider's continued commitment to achieving industry best practice.

### 3.4.1 Key considerations

Guideline sections 3.5 to 3.10 are based on the legislative requirements under section 95(3) of the Act. The relationship between these guideline sections is illustrated in the supporting information which accompanies this guideline. In preparing the plan, it is important to note:

- the provider must submit all relevant and available information for the service, and each scheme associated with it, to meet the legislative requirements of the Act. Where there is insufficient information about the plan to make a decision, the regulator may request additional information (refer to guideline section 4.2.2)
- the plan must contain the necessary information to fulfil each criteria, outlined in the shaded boxes under guideline sections 3.5 to 3.10, for the service and each scheme associated with it, to enable the regulator to make a decision about the plan
- the criteria are further explained in the addressing the criteria section. This section provides an indication of the type of information the regulator believes will assist in fulfilling the requirements of the criteria
  - the provider may submit information on all or some of the items listed in the addressing the criteria section. The level of information provided in the plan is dependant on the service, its size and complexity and the availability of information for all or some of the schemes associated with it
- the structure of the plan will vary from provider to provider. It is up to the provider to determine the best way to present the information. It may be worth considering the plan as a narrative on how the provider manages its service from catchment to the consumer to protect public health
- in some cases, further information may be required to address particular criteria for a scheme associated with the service, where the relevant information was not available at the time the plan was submitted:
  - the Risk Management Improvement Program<sup>11</sup> is an acceptable approach for addressing additional information requirements for one or more criteria for a scheme, where the information was unavailable at the time of the plan submission, and additional risk management measures that are required in the short, medium or long-term to address unacceptable risks to protect public health
  - the Risk Management Improvement Program must detail the outcomes to be achieved (for example, the type of information required or risk management measure to be put in place), the actions to be undertaken to achieve the outcomes (for example, the process for obtaining information or steps to be followed to put additional measures in place) and the timeframes in which the actions are to be completed
  - the Risk Management Improvement Program is part of the plan and forms part of the regulator's decision with respect to the appropriateness of the plan to protect public health.

### 3.4.2 Stakeholders

An integrated management approach with the collaboration from all relevant stakeholders is essential for effective drinking water quality management. Throughout guideline sections 3.5 to 3.10, reference is made to stakeholders in the relevant criteria. Key stakeholders who are actively involved and therefore could affect the quality of the drinking water, or be affected by the decisions or activities of the service or each scheme associated with the service are required to be identified in the plan. Appropriate mechanisms and levels of stakeholder engagement (for example, meetings, workshops, newsletters etc) should also be developed. Whilst community is an important stakeholder in the quality of drinking water supply, a general community consultation process is not considered necessary in the preparation of the plan, in most circumstances.

The following are examples of the types of stakeholders that should be included:

- upstream suppliers

---

<sup>11</sup> Refer to guideline section 3.9.4.

- catchment users and/or managers
- downstream customers
- vulnerable customers
- material suppliers
- the community served
- internal organisational units
- regulatory agencies or statutory authorities (for example, regulator, catchment boards).

### 3.5 Registered service details

Section 95(3)(b) of the Act states the plan must:

- (i) state the registered services to which the plan applies.

This guideline section requires the registered service details to be provided with the intent being to clearly identify the service, the scheme(s) and the communities to which the plan applies.

#### 3.5.1 Service description

##### Criteria

- The plan must contain information on the registered service, including the:
  - service provider identification number (SPID)
  - service provider name and contact details. If the service provider is not the operator, then the operator's name and contact details must also be provided
  - name of each scheme to which the plan applies
  - name of the communities that are supplied including the current and future (next 10 years) populations, connections and demands.

##### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- details of the service (for example, SPID, name and contact details, name of scheme(s)) could be provided using the Drinking Water Quality Management Plan Approval Application form
- current and future projections should include
  - name of the community served by the scheme
  - current population of the community served (i.e. number of persons), number of connections and the water demand (i.e. volume)
  - projected future population of that community (i.e. number of persons), likely increase in the number of connections and the likely increase in water demand for the next 10 years (i.e. volume).

### 3.6 Details of infrastructure for providing the service

Section 95(3)(b) of the Act states the plan must:

- (ii) include details of the infrastructure for providing the services.

Understanding the infrastructure of the service is a critical first step for identifying the hazards and hazardous events that can compromise drinking water quality, and ensuring that risks are addressed.

For the purposes of this guideline, infrastructure details include all the key components that form part of the service, from catchment to consumer, including:

- source
- treatment process

- disinfection process
- distribution and reticulation system including reservoirs and pump stations
- stakeholders (who are relevant to drinking water quality management).

This guideline section outlines the infrastructure details of the service that are required to be provided. The plan must contain sufficient information on infrastructure details for, and the communities served by, each scheme associated with the service. The plan must contain sufficient information to demonstrate that the provider has an understanding of each scheme and its operation.

**Criteria**

- The plan must describe the details of the infrastructure including the following:
- A schematic layout for each scheme must be included in the plan and must:
  - be representative of the scheme as at the date of the submission of the plan
  - include all components of the scheme from catchment to consumer (even when a bulk supplier exists upstream of the distributor)
  - show the linkages between the major infrastructure elements including sources, treatment plants, reservoirs, pump stations and re-chlorination facilities
  - include the locations of changes in infrastructure ownership and operational responsibility.
- Source details for each scheme must be provided in the plan. These details must contain information on the:
  - water source(s) including
    - name
    - characteristics
    - performance
  - source infrastructure.
- Treatment process details for each drinking water source must be provided in the plan. These details must contain information on:
  - the process steps
  - the relationship between each step design capacity
  - operation
  - current loading
  - availability of stand-by equipment
  - proportion of flow from each source
  - proportion of scheme supply distribution area
  - a list of chemicals (if added).
- A description of any variations to process operation (for example, bypassing a process step) must be included in the plan.
- A schematic(s) representing the treatment process(es) must be included in the plan.
- Any sources that do not undergo a treatment process must be identified and an explanation as to why no treatment process exists must be included in the plan.
- Disinfection process(es) for each drinking water source must be provided in the plan. These details must include:
  - location
  - type
  - operation.

Any sources that do not undergo a disinfection process must be identified and an explanation as to why no disinfection process exists must be included in the plan.

- Details of the distribution and reticulation system must be included in the plan. These must include the:
  - extent
  - characteristics
  - operation.
- Key stakeholders, who have been actively involved in the management of drinking water quality, and their relevance, must be identified for each scheme and detailed in the plan

### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- Schematics should generally be at the level illustrated in the supporting information which accompanies this guideline.
  - The details of each water source should include:
    - name
    - proportion of scheme supply
    - historical performance (for example, does it run dry or to very low levels)
    - water quality issues (for example, blue-green algae, pesticides, fluoride, radiological agent, nitrates etc.).
  - The details of the source infrastructure should include (where appropriate):
    - for surface water:
      - intake location
      - type of intake structure (for example, flexible, fixed)
      - multiple off take level capability
      - protection from debris and flood damage
    - for groundwater: pre-treatment (for example, aeration for groundwater):
      - bore location, depth
      - aquifer description:
        - depth and thickness
        - confined/unconfined
        - fast or slow response to events on surface
      - bore construction details, for example:
        - casing (for example, depth, diameter, material, age)
        - borehead details to prevent contamination.
  - Details of the treatment process(es) used should include:
    - flocculants used
    - type of sedimentation
    - chemical correction
    - filtration and type of filter media
    - fluoridation.
  - The schematic of the treatment process(es) should show the linkages between each treatment step.
  - Details of the disinfection process(es) should include:
-

- location (including re-disinfection facilities)
- type of disinfection and make and age of infrastructure
- chemical dosing (where applicable)
- dose rate and dosing arrangements (for example, fixed, flow-paced, residual analyser)
- target residual levels (where applicable)
- duty/stand-by available and description:
  - alarms (for example, failure, low/high residual)
  - auto shut-off arrangements.
- Details of the distribution and reticulation system should include:
  - pipe material and age range
  - approximate proportion of total length of each material
  - areas where potential long detention periods could be expected
  - areas where low pressure could be expected
  - details of reservoirs (for example, name, type, capacity, roofed Y/N)
  - details of pump stations (for example, number and location).
- Details of key stakeholders<sup>12</sup> who have been actively involved in the management of drinking water infrastructure and their relevance for each scheme.

### 3.7 Identify hazards and hazardous events

Section 95(3)(b) of the Act states the plan must:

- (iii) identify the hazards and hazardous events the drinking water service provider considers may affect the quality of water to which the services relate.

A number of tasks need to be undertaken to fulfil this legislative requirement including:

- information gathering
- hazard identification.

The criterion that must be met for each task and information on addressing the criteria is provided below.

Once a suitable understanding of the infrastructure of the service has been established, the identification of all potential hazards and hazardous events that may occur at each component of the scheme (for example, catchment, source, treatment and distribution system) must be undertaken. This must also include hazards and hazardous events that may be outside the control of the provider, and that may occur within the catchment or a bulk supply source.

In this context:

- a **hazard** is a biological, chemical, physical or radiological agent that has the potential to cause harm (ADWG, 2004)
- a **hazardous event** is an incident or situation that can lead to the presence of a hazard (what can happen and how) (ADWG, 2004).

The hazards and hazardous events that may affect the quality of drinking water for each scheme within a service may vary. Therefore it is important to base the hazard identification on the best available information relevant to each scheme (for example, records and people with the relevant water quality and catchment skills and knowledge).

---

<sup>12</sup> Refer to guideline section 3.4.2 for further details on stakeholders. Stakeholders would generally include the community, however a general community consultation process is not considered necessary in all circumstances.

### 3.7.1 Information gathering—water quality and catchment characteristics

In addition to the details of infrastructure, it is important to include information on the water quality and catchment characteristics to enable a complete assessment of the hazards and hazardous events for each scheme associated with the service.

#### Water quality information

All available information should be assessed to gain an understanding of the source water<sup>13</sup> and system performance. Information should be examined both over time and following specific events such as heavy rainfall.

The intent of this guideline section is to use available and relevant water quality information, data, customer complaints, event information etc, to help identify any potential hazards and hazardous events that may impact on drinking water quality. When multiple providers are involved, an overview of upstream (for example, bulk supplier) and/or downstream (for example, distributor) water quality information relevant to the service is required.

#### Criteria

- The plan must include a summary of the analysis and interpretation of available and relevant water quality information.
- Where multiple providers are involved in providing the water supply, the above summary must to the best of their knowledge, include relevant water quality information on the immediate upstream (for example, bulk supplier) and/or immediate downstream (for example, distributor) system(s).

#### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- a summary of water quality characteristics should include:
  - source water
  - treated water
  - supplied water:
    - number of samples, maximum/minimum/median/standard deviation, annual values for the above (where appropriate)
- a commentary on figures or information given, should include reasons for:
  - trends
  - exceedences
  - major variations
  - abnormal results
  - low number of results or no results for some relevant characteristics
  - potential problems
- a commentary on the validity of the data should include:
  - position of person that takes the samples, transport arrangements for off-site analysis, the testing laboratory
  - whether there have been any significant changes such as catchment characteristics, treatment process(es) during or since the period the tests were undertaken
- summary information and commentary on any water quality complaints that may have impacted on public health, should include:
  - the nature of the complaints by category (for example, dirty water, suspected illness)

<sup>13</sup> For a drinking water service that has multiple providers, source water may include the raw water entering the treatment process or treated water entering a transmission or distribution and reticulation system.

- proportion of customers affected
- frequency of occurrence
- likely cause of complaints
- It would also be desirable to provide the history of water quality complaints (relevant to the safety of the supply). For example: Suburb A experiences 30 dirty water complaints each week over the wet season. The provider believes that the dirty water could impair disinfection residual and therefore result in excessive *E. coli*.

### Catchment characteristics

The aim of this guideline section is to provide a broad qualitative description of the catchment characteristics. It is not anticipated that providers that are responsible for transmission or distribution will need to undertake a catchment characterisation exercise. However, the information necessary to underpin this hazard identification process should be available through the upstream entity (for example, a bulk supplier).

#### Criteria

- The catchment characteristics for each scheme's water source must be documented in the plan. This includes a description of:
  - catchment area or groundwater recharge area
  - topography
  - main geological features
  - climatic features
  - land use.

### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- details on the catchment characteristics should include:
  - soil type
  - annual and monthly rainfall (for example, average, maximum, minimum)
  - incidence of flooding and bushfire
  - predominant vegetation types
  - urban settlements, population and location
  - agricultural, industrial, mining and recreational activities
  - planned future activities which may impact on water quality.

### 3.7.2 Hazard identification

The plan must contain sufficient detail to indicate that the provider has identified all the hazards and hazardous events that might affect each scheme component (for example, catchment, sources, treatment and distribution system). This includes:

- all appropriate point and diffuse sources of pollution, continuous, intermittent and seasonal pollution patterns, including infrequent and extreme events
- treatment plant failure, operational error or incorrect chemical dosing
- hazards that are not under the direct control of the provider but which may impact on drinking water quality.

Where multiple providers are involved, the identification of hazards and hazardous events for each provider's plan should include those identified by the other entities (to the extent they are relevant). To ensure consistency between plans and minimise duplication of effort this information should be obtained from the other provider (where possible).

Each provider must take into account the hazards which are likely to occur, based on the infrastructure details, catchment characteristics and relevant water quality information for each scheme within the service.

The identification of potential hazards, hazardous events and the subsequent risk assessment should be undertaken by those that have the relevant skills and experience to fully assess the hazards that may affect drinking water quality. The hazard identification process should involve other members of the organisation that have the knowledge of each scheme within the service. Members may include management, operations and maintenance staff, laboratory staff, external consultants, multiple providers, stakeholders and consumer groups (where applicable). Staff responsible for undertaking the hazard identification process and risk assessment should also be involved with developing, verifying and implementing the plan.

Refer to the supporting information which accompanies this guideline for a list of examples of potential sources of hazards and hazardous events.

#### Criteria

- The hazards and hazardous events and the sources of the hazards and hazardous events that could adversely affect water quality must be documented in the plan, including those affecting the:
  - catchment
  - sourcing infrastructure
  - treatment plants
  - disinfection process(es)
  - distribution system.
- When multiple providers are involved, the plan must to the best of their knowledge, include the hazards and hazardous events and the sources of the hazards and hazardous events associated with the operations and water quality management processes of the other entities' systems which the provider considers could impact on the service.
- Whole of service hazards and hazardous events and the sources of the hazards and hazardous events must be documented in the plan.
- The plan must detail the personnel (i.e. position) responsible for the hazard identification and risk assessment process, their roles and responsibilities and how knowledge of the actual day to day operations of the scheme(s) has been included in this process.
- Key stakeholders who have been actively involved in the hazard identification process, their role and rationale for inclusion must be documented in the plan.

#### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- details of the hazards and hazardous events<sup>14</sup> should include those arising from:
  - catchment activities, for example:
    - alternative water sources
    - polluted discharges
    - contaminated runoff
    - mining
    - agriculture (for example, grazing animals, pesticide spraying, fertiliser application etc)
    - intense feedlots/dairy
    - environmental events (for example, bush fire, storm events, drought etc)

<sup>14</sup> Refer to the supporting information which accompanies this guideline for a list of potential sources of hazards and hazardous events.

- high levels of naturally occurring fluoride or radionuclides
  - human access to catchments and recreational use of storages
  - any potential sewage or recycled water discharges within the catchment
  - land uses (for example, landfill, forestry, industry, roads, urban development)
  - PRW used for augmenting a drinking water supply
  - algal blooms within raw or source water storages
  - spillage and/or accidents in catchment
  - residence time, short circuiting and stratification of dams
  - sourcing infrastructure, for example:
    - for surface water:
      - intake details (for example, operation, ability to change levels etc)
      - raw water or source water pipeline (for example, breakages)
    - for groundwater:
      - bore details (for example, age, construction, susceptibility to ingress of poor quality water etc)
  - treatment plant, for example:
    - equipment failure and/or availability of stand-by
    - treatment plant component capacity exceedences
    - operational excursions
    - inadequate treatment processes
    - use of chemicals (for example, storage, dosage etc)
    - natural disasters
  - disinfection or lack of disinfection process(es), for example:
    - equipment failure and/or availability of stand-by
    - operational excursions
    - disinfection by-products
    - no, or inadequate, disinfection process(es)
  - distribution system, for example:
    - equipment failure and/or availability of stand-by
    - operational excursions
    - pressure fluctuations
    - no, or inadequate, disinfectant residual
    - maintenance practices
    - aging infrastructure
    - backflow
  - upstream and/or downstream infrastructure, for example:
    - re-chlorination facilities
    - balance storages
    - long delivery mains
    - potential low pressure areas
    - alternative and/or varying sources
-

- catchment characteristics
- treatment facilities
- whole of service context, for example:
  - organisation wide issues (for example, amalgamation or formation of distributor and/or retailer)
  - workforce structure, skills retention, etc
- personnel involved in the hazard identification and risk assessment process, for example:
  - role in the process
  - expertise
  - knowledge of the service.
- Details of key stakeholders who have been actively involved in the hazard identification process, their role and rationale for inclusion.

### 3.8 Assessment of risks

Section 95(3)(b) of the Act states the plan must:

(iv) include an assessment of the risks posed by the hazards and hazardous events.

Following the identification of the hazards and hazardous events relevant to each scheme, an assessment of the risk posed by each hazard is necessary in order to correctly apply risk management measures.

Risk is defined as the likelihood of identified hazards causing harm in exposed populations in a specified timeframe, including the severity of the consequences (i.e. risk = likelihood x consequence) (ADWG, 2004).

For drinking water supplies, risk assessments need to be undertaken in two stages:

- Maximum risk—assumes no preventive measures are in place<sup>15</sup>
- Residual risk—includes the mitigating effects of existing preventive measures.

Preventive measures are those actions, activities and processes that are used to prevent hazardous events from occurring or reduce the risks to acceptable levels. Refer to the supporting information which accompanies this guideline for a list of preventive measures. The supporting information also provides an example of a risk methodology table.

For multiple providers, the risk assessment of each provider should consider the maximum and residual risk assessment results from the other provider(s) to the extent they are relevant.

Uncertainty relates to the level of confidence that is placed in the risk assessment and arises from issues such as:

- lack of complete knowledge (ADWG, 2004)

or

- variability of information (ADWG, 2004).

The plan should recognise any uncertainties surrounding the risk assessment and factor these into the preventive measures adopted.

The plan must contain sufficient information to indicate that the provider's risk assessment outcomes have addressed the hazards and hazardous events identified.

---

<sup>15</sup> At the very least, the maximum risk should be evaluated on the basis that no treatment is provided, i.e. raw water being supplied to the community. Assessing maximum risk level prioritises risks and assists with the development of emergency and incident plans in the event that major treatment components or barriers fail. It also helps to establish the critical preventive measures across the service to guide appropriate operational procedures and monitoring to ensure these critical measures are continuously effective.

### Criteria

- The plan must detail the risk assessment methodology used for each scheme including:
  - reference to a published version such as ADWG, HACCP, AS/NZS ISO 31000-2009
  - if a published version has not been used, a description of the methodology which has been used must be provided
  - the definition of likelihood, consequence and risk level used
  - an explanation of the acceptable risk level and the rationale for this selection.
- Details of the risk assessment results for each scheme's identified hazards and hazardous events must be documented in the plan, including:
  - hazard
  - source of hazard and hazardous event
  - maximum risk level or equivalent process<sup>16</sup> (i.e. without existing barriers in place for example, treatment and/or disinfection)
  - existing preventive measures including multiple barriers (i.e. treatment process steps)
  - residual risk level (i.e. with existing barriers in place for example, treatment and/or disinfection)
  - any uncertainties.
- Key stakeholders who have been actively involved in the risk assessment process, their role and rationale for inclusion must be documented in the plan.
- Where multiple providers are involved, the plan must, to the best of their knowledge, explain how the relevant maximum and residual risk assessment results from other provider's service(s) have been considered.

### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- Details of the risk assessment should include:
  - if different risk assessment methodologies are used for different schemes across the service, an explanation as to why
  - if significant future changes have been noted (for example, population growth), a scenario in the risk assessment
  - how the risk assessment process was conducted (for example, workshop, interviews, data analysis etc)
  - the treatment performance assumed for each multiple barrier and the rationale
  - key stakeholders.
- Where risks arise from other providers' systems or activities, the risk assessment should (where relevant):
  - consider the risk assessment results from the other provider<sup>17</sup>
  - be evaluated in the context of the risk and the measures in place by both providers
  - include maximum and residual risks from the other provider that impact on the service
  - include an assessment of the methodology adopted for the service.

<sup>16</sup> A process that assesses unmitigated risks or the situation where there are no barriers or existing control measures in place.

<sup>17</sup> Where the other provider's risk assessment results are not available, an estimate of the risks likely to be transferred from the other provider's system may need to be undertaken.

### 3.9 Managing risks

Section 95(3)(b) of the Act states the plan must:

- (v) demonstrate how the drinking water service provider intends to manage the risks posed by the hazards and hazardous events.

In completing the risk assessment, the effectiveness of any existing preventive measures would have been evaluated to determine the level of residual risk (for example, low, medium, high or 1, 2, 3) for each identified hazard and any uncertainties in the results. The level of each residual risk will then need to be assessed as acceptable or unacceptable. The unacceptable residual risks will require the identification of (further) measures or actions to reduce them to an acceptable level.

It is the responsibility of the provider to determine, within the circumstances of its service and each scheme associated with the service, the appropriate measures or actions for managing risks to drinking water. These measures or actions include internal organisational measures, such as infrastructure improvements, operational procedures, workforce skills and knowledge, information management, incident and emergency management protocols or procedures, and actions by external organisations or stakeholders.

The plan must demonstrate the provider has appropriate measures or actions in place to adequately manage the identified risks and protect public health. To achieve this, the plan will need to document how:

- the existing preventive measures will be managed to ensure their ongoing effectiveness
- unacceptable residual risks will be addressed in both the short and long-term
- uncertainties in the risk assessment will be reduced
- incidents and emergencies will be managed
- information will be handled to support the management of risks.

#### 3.9.1 Risk management measures

The provider must demonstrate how they intend to manage the identified risks posed by the identified hazards and hazardous events.

##### Criteria

- The plan must contain an overall list of all the existing and proposed preventive actions or measures managed by the provider to achieve acceptable residual risks in the short and longer-term.
- Where the provider relies on an external organisation to manage a risk to their service, the plan must document what the preventive actions or measures are, and what arrangements are in place with the external organisation to ensure the measures remain effective.

##### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- a description of short-term measures should include:
  - replacement of equipment
  - operational procedures
  - improving workforce awareness or use of external expertise
  - information sharing processes
  - management of existing measures
- a description of longer-term measures should include:
  - alternate sourcing arrangements
  - infrastructure upgrades
  - workforce composition
  - skills gaps and training needs

- training and skills development
- water quality management skills in the organisation through recruitment, succession planning, mentoring etc
- ensuring that staff are made fully aware of their responsibilities to drinking water quality (for example, through position descriptions)
- ensuring that contractors and/or new staff have appropriate skills and knowledge
- when multiple providers are involved in the supply of recycled water to augment a drinking water supply, a summary of arrangements should include:
  - contracts, and agreements
  - service level agreements relating to volume and water quality
  - other relevant strategies and/or plans, for example:
    - communication or stakeholder strategies between providers
    - recycled water management plans and/or other provider’s drinking water quality management plans
- when external organisations are relied on to manage a risk to the service, details may include:
  - preventive actions or measures including:
    - controlling stock access to source water
    - catchment land use controls and/or practices
  - arrangements with the external organisation to ensure the measures remain effective:
    - contracts, agreements
    - agreed plans and/or protocols.

### 3.9.2 Operation and maintenance procedures

Operation and maintenance procedures formalise the day-to-day activities and help to ensure that all preventive measures are effective in managing the identified risks. While operation and maintenance procedures are usually developed to manage infrastructure related aspects of the service, these procedures may also address program areas such as stakeholder or catchment management.

The plan must demonstrate the preventive measures identified in the risk assessment process, and used to achieve a documented residual risk, are supported and managed by appropriate operation and maintenance procedures. These procedures must be identified, documented and implemented.

In preparing the plan, providers should review the current practices to identify any procedures that need to be improved or upgraded and detail how this will be achieved in the Risk Management Improvement Program (refer guideline section 3.9.4 for further information).

Refer to the supporting information which accompanies this guideline for a list of potential documented operation and maintenance procedures.

#### Criteria

- The plan must contain, for each existing preventive measure identified in the risk assessment as a measure for achieving the documented residual risk, a list of the documented operation and maintenance (or other) procedures that are required to ensure the integrity of the measures, including:
  - title
  - date last revised
  - the process used for maintaining the documented procedures
  - the process for implementing the procedures.

### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- details of the operation procedures should include:
  - a summary of routine operational practices, including changes to routine activities during abnormal conditions (for example, flooding)
- a summary of maintenance practices:
  - asset group
  - maintenance activity
  - frequency
  - reference to a documented procedure (if applicable)
- details of the operation and maintenance procedures:
  - date that each procedure was reviewed and when any proposed new procedures will be completed
  - processes to ensure that documented procedures are accepted and implemented by staff
  - processes for documentation review, update and distribution to relevant staff
- details of procedures or practices for ensuring any other measures relied on to achieve acceptable levels of risks (for example, external organisation actions, land use planning and management) are maintained.

### 3.9.3 Management of incidents and emergencies

In addition to having preventive measures for managing risk, effective incident and emergency communication and response protocols are also essential to protect public health and important to maintain community confidence. Protocols for both internal and external communications should be established in advance.

The plan must define potential incidents and emergencies and responses to these events, including communication protocols for internal and external notification.

Staff training and follow-up investigations are also important aspects of incident and emergency management and, therefore, the process for training employees for emergency situations and the protocols for investigating incidents and emergencies should also be established and included in the plan.

#### Criteria

- The process for managing drinking water incidents and emergencies must be described in the plan, including:
  - incidents and emergencies
  - the level of emergency (for example, green, amber, red or level 1, 2)
  - summary of action(s) taken for each level including emergency contacts
  - internal and external communication processes and protocols , including those with other key stakeholders that are actively involved
  - responsible positions.
- When multiple providers are involved in providing drinking water, the plan must explain how incidents and emergencies are managed between the entities.

### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- details on managing drinking water incidents and emergencies should include:
  - defining the emergency and its incident level (for example, green, amber, red or level 1, 2)
  - links to local or regional emergency or disaster management plans

- documented procedures (for example, for providing safe drinking water to customers when a high *E. coli* test result is received, or loss of supply)
- a list of people to be contacted during emergencies, including:
  - incident or emergency type
  - organisation (including the department):
    - contact position(s)
    - contact details
    - communication protocols
    - level of engagement
- the processes for:
  - training employees for emergency situations
  - testing emergency response procedures and frequencies
  - incident investigation and how corrective and/or preventive measures are implemented
  - revising emergency protocols as necessary
- when multiple providers are involved in responding to incidents and emergencies, details on how each providers' incident management protocols integrate to demonstrate collaborative communication arrangements in managing risks, for example:
  - communication protocols
  - emergency response plan protocols and procedures
  - incident reporting and management protocols and procedures
  - relationship between monitoring programs
  - response measures to incidents.

### 3.9.4 Risk Management Improvement Program

The plan must:

- identify the hazards and hazardous events
- assess the risks (maximum risk and residual risk) posed to the quality of drinking water (risk assessment process)
- demonstrate how they intend to manage the risks identified through the risk assessment process.

The results of the risk assessment process should give the provider an indication of the types of risks that need to be managed across the service and each scheme associated with the service. Information on the measures that the provider has in place to manage these risks should be documented in response to the legislative requirement—managing risks (that is, guideline sections 3.9.1 (risk management measures) through to 3.9.3 (management of incidents and emergencies)).

It is recognised that for some risks identified in the plan for the service and each scheme associated with the service, management measures may not be in place at the time the plan is submitted for various reasons or external factors beyond the control of the provider. The provider is responsible for managing these risks, including unacceptable risks, to protect public health. In this situation, the provider is required to identify interim, short-term to long-term management measures as part of the plan. The risk assessment process should also assist the provider in prioritising these additional or improved measures or actions.

The Risk Management Improvement Program (the program) is a mechanism for the provider to demonstrate to the regulator how it will address these risks identified in the plan. The program must accompany the provider's plan and outline the interim, short-term to long-term management measures and actions and the implementation timeframes.

The program may include a wide range of measures or actions for improving the management of risks, such as:

- unknowns in the system description
- high uncertainties from the risk assessment
- risks that remain high at the current residual risk level
- operational monitoring and process controls
- water quality performance
- customer complaint performance
- required upgrades following any emergencies or incidents
- skills and staff levels
- areas that performed poorly during audit and review
- stakeholder engagement.

It is the provider's responsibility to ensure that funding or commitments to funding for any measures or actions identified in the program are secured through their organisation's budget processes. This will be an important issue for providers, as the program will be assessed by the regulator as part of the plan and the timing for implementing measures or actions will be a consideration. The regulator may choose to place conditions (for example, progress reports) relating to the measures, strategies or actions of the program. The consideration of the program by the regulator will not commit the state to funding in any measures or actions within the program.

Similarly, it is the responsibility of the provider to submit relevant and available information to meet the legislative requirements for the service and each scheme associated with the service. However, it is recognised in certain circumstances, the provider's ability to submit all relevant information relating to the service and each scheme associated with the service may be impeded due to external factors which are beyond the control of the provider. These factors may influence the availability of information on a scheme, or service, in terms of:

- common risk assessment methodology
- water quality information
- hazard identification
- risk assessment
- management of risks
- common protocols, procedures for managing risks, communication, training and awareness
- adequacy of the monitoring program.

A provider should attempt to provide all available information to meet the legislative requirements. Where further information is required for a service or scheme, the provider must articulate how the information will be provided to the regulator, including timeframes for completion and this can be done through the program.

Insufficient time to prepare the plan is not considered an external factor.

**Criteria**

- The plan, through the program, must describe the management measures proposed for each unacceptable residual risk. The process for providing the relevant information to the regulator must also be described. The description must include:
  - measures, actions, strategies or processes
  - priority for implementation
  - timeframe
  - other factors, for example, responsibilities between the provider and third parties and/or other stakeholders.

### Addressing the criteria

When addressing the above criteria, the provider may combine the above requirements in the program. In developing the program, consideration should be given, but not limited, to:

- the prioritised measures, actions, strategies or process(es) including:
  - interim or short-term management measures proposed for each unacceptable residual risk
  - permanent or long-term management measures proposed for each unacceptable residual risk
  - strategies or process(es) for providing the relevant information to the regulator
- timeframe for delivery of measures, actions, strategies and process(es)
- a rationale for the implementation schedule
- funding available (yes/no), if no funding is available, then consider other alternatives to achieving the outcome
- position responsible for delivering the measures, actions, strategies or process(es).

### 3.9.5 Service wide support—information management

Information relating to drinking water quality must be appropriately managed so that it is readily accessible, accurate, reliable, timely and up to date. Providers should:

- maintain adequate records of operational activities and decisions that could impact on the management of drinking water quality
- have an information management system for document control, data management, record keeping and internal and external reporting. Document retention times should be based on any relevant regulatory requirements and to satisfy auditing needs.

Although records may not need to be included as part of the plan, they should be available to submit to the regulator on request.

#### Criteria

- The plan must describe the information management, record keeping and reporting processes relevant to drinking water quality management, including how they address:
  - accessibility
  - currency
  - record retention requirements.

### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- a description on the information management, record keeping and reporting processes should include:
  - information type (for example, manuals and procedures) and format (for example, hardcopy/electronic)
  - the document control process
  - responsible position(s)
  - processes for internal and external (including regulatory) reporting.

### 3.10 Operational and verification monitoring programs

Section 95(3)(b) of the Act states the plan must:

- (vi) include details of the operational and verification monitoring programs under the plan including the parameters to be used for indicating compliance with the plan and the water quality criteria for drinking water.

Operational and verification monitoring programs are required to support the management measures for the identified risks. The plan must contain sufficient information to demonstrate that the provider has appropriate operational and verification monitoring in place.

Monitoring should have a whole of scheme focus and include each of the components (for example, treatment, transmission and reticulation).

It is the provider's responsibility to determine the operational and verification monitoring program relevant for each scheme associated with the service.

Until the approved plan for the service is in place, the provider is responsible for undertaking water quality monitoring and reporting in accordance with the Drinking Water Service Provider Monitoring and Reporting Requirement Notice (the notice) issued by the regulator in December 2008 pursuant to section 630 of the Act. It is anticipated that the information collated as part of this process by the provider, together with the results of the hazard identification and risk assessment process should identify:

- whether the current operational and verification monitoring programs are appropriate and adequate to protect public health
- any deficiencies in the existing operational and verification monitoring programs of each scheme associated with the service
- improvements or upgrades to the existing operational and verification monitoring programs necessary to address these deficiencies.

The operational and verification monitoring programs contained in the plan should address all hazards and risks that may impact on each scheme associated with the service to protect public health.

The provider is responsible for complying with the operational and verification monitoring program under the plan and the water quality criteria generally.

The Water Quality and Reporting Guideline for a Drinking Water Service<sup>18</sup> articulates the water quality criteria for drinking water. It identifies the parameters that must be included in the verification monitoring program of a service, in accordance with the Public Health Regulation. It also sets out the criteria made by the regulator that must be complied with for other parameters where they are included in the verification monitoring program. The water quality criteria are defined under schedule 3 of the Act as:

for drinking water, means all of the following:

- (i) the standards for the quality of drinking water prescribed in a regulation under the Public Health Act
- (ii) the criteria stated in a guideline, if any, made by the regulator about the quality of drinking water
- (iii) the criteria for the quality of drinking water stated in a condition applying to a drinking water quality management plan.

The ADWG also provides information on the types of parameters, monitoring methodology, sampling locations and sampling frequency that should be considered, along with desired water quality criteria or standards that should be achieved.

---

<sup>18</sup> The Water Quality and Reporting Guideline for a Drinking Water Service can be accessed online at <[www.derm.qld.gov.au](http://www.derm.qld.gov.au)>

### 3.10.1 Operational monitoring

Operational monitoring is a planned sequence of observations or measurements that ensure that the system, including critical control points, is operating within performance limits in 'real time'. It is an important component of an overall monitoring program and is used to:

- confirm the system is performing within the operational tolerance limits
- control process elements
- provide for corrective actions in the short-term.

An effective monitoring program should meet the following requirements:

- provide an immediate indication of performance
- include appropriate surrogates and indicators to enable continuous monitoring
- be used to trigger immediate short-term corrective actions to maintain drinking water quality
- monitor with sufficient frequency to reveal any failures in a timely manner (with sufficient time to act)
- monitor any significant hazards identified in the risk assessment (for surrogates or indicators of those hazards).

#### Criteria

- The plan must contain details of the operational monitoring program, including:
  - a link to the process step or operational function
  - the parameter being tested
  - location of monitoring
  - frequency
  - summary of how excursions are managed and/or corrective action is taken.
- The plan must describe why the operational monitoring program is appropriate to confirm and maintain the effective operation of the existing preventive measures.

#### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- details of the operational monitoring program should include:
  - operational monitoring details, for example:
    - the parameter being tested
    - sample method (for example, grab, online)
    - the process for sampling, routine analysis and transportation
    - analysis method
    - interpretation and communication of results (including quality control)
  - process for long-term evaluations of trends in monitoring results including use of results to influence and improve management of the drinking water service
  - referenced documented procedures, for example:
    - sampling procedures
    - data handling procedures
    - response to excursions
    - communication procedures

- contractual obligations
- list of plant operating procedures
- details of the operational monitoring program in relation to the identified preventive measures including:
  - the parameter
  - the test location
  - identified target and critical levels
  - the rationale for the monitoring program (including parameter selection).

### 3.10.2 Verification monitoring

Verification monitoring is used to confirm product quality at the point of supply, compliance with water quality criteria and to identify deficiencies in existing preventive or control measures. It is an assessment of the performance of the scheme and unlike operational monitoring, it does not occur in real time. It is used to confirm product quality, compliance with water quality criteria and to identify deficiencies in existing control measures.

The water quality criteria for the service must include the water quality criteria set by Queensland Health and any set by the regulator. Other parameters identified for monitoring the safety of the drinking water for individual schemes must also be included.

#### Criteria

- The plan must contain details of the verification monitoring program including:
  - the parameter being tested
  - location of monitoring
  - frequency
  - summary of how excursions are managed and/or corrective action is taken.
- The plan must also describe why the verification monitoring program is appropriate to confirm that the drinking water complies with the water quality criteria for drinking water (including the rationale for the choice of the parameters).

#### Addressing the criteria

When addressing the above criteria consideration should be given, but not limited, to:

- details of the verification monitoring program should include:
  - a tabulation of verification monitoring including:
    - ADWG value
    - analysing authority (for example, National Association of Testing Authority accredited laboratory, in-house)
    - other system monitoring measures (for example, customer complaints)
- description on the:
  - monitoring locations and the rationale for their selections
  - process for sampling, routine analysis and transportation of samples
  - interpretation and communication of results (including quality control)
  - process for long-term evaluation of trends in monitoring results
- referencing documented procedures, for example:
  - sampling procedures
  - data handling procedures

- response to excursions
- communication procedures, contractual obligations
- list of plant operating procedures.

### **3.11 Best practice recommendations**

This guideline has been developed to provide information to providers about preparing the plan. The plan must reflect the requirements of the Act as stated in guideline sections 3.5 to 3.10. Providers, however, can choose to expand the plan criteria by incorporating some or all of the following best practice recommendations. These recommendations are based on the ADWG elements and sub-elements and reflect the current practices used within the industry to promote a safe supply of drinking water. However, as these recommendations are not requirements under the Act they will not be considered in the assessment of the plan. These recommendations include:

- commitment to drinking water quality management
- employee awareness and training
- research and development
- review and continual improvement.

#### **3.11.1 Commitment to drinking water quality management**

##### **Drinking water quality policy**

The purpose of a drinking water quality policy is for the organisation to demonstrate a commitment to protecting public health. Any policy statement for drinking water should provide a basis for the development of detailed guiding principles, procedures and implementation strategies.

To meet this recommendation, the plan should include a drinking water policy statement. This statement should address broad issues and requirements as outlined in ADWG, such as:

- commitment to the application of a risk management approach
- communication and engagement with employees and the public
- intention to adopt or work towards best practice and multiple barriers
- continuous improvement in managing drinking water.

##### **Regulatory and formal requirements**

There are a number of requirements placed on providers ranging from legislative and regulatory requirements to industry standards and codes of practice. Providers may also enter into formal agreements with their customers, stakeholders, other water service providers and recycled water providers.

The provider should demonstrate their understanding of the regulatory requirements, and any formal agreements associated with the service.

To meet this recommendation, the plan should include a list of regulatory requirements and/or formal agreements for the service.

#### **3.11.2 Employee awareness and training**

##### **Employee awareness and involvement**

It is vital to ensure that all staff and contractors fully understand the operations of the service and how their actions influence the protection of public health. The provider should have appropriate mechanisms and procedures in place to ensure staff across the organisation are aware of the key issues that influence the management of the service.

As mentioned in the ADWG, all staff should be aware of issues such as:

- drinking water quality policy of the organisation, regulatory and legislative requirements
- roles and responsibilities
- how their actions impact on water quality and public health.

Measures to enhance employee awareness may include:

- involving staff in the development of procedures and decision making
- induction training for employees and contractors, which may include a briefing on the ADWG, drinking water quality policy and the plan
- use of regular staff meetings (tool box meetings).

All staff awareness mechanisms should be recorded. This may include training material, date of training and attendance records.

To meet this recommendation, the plan should document what mechanisms are used to maintain employee awareness and involvement.

### **3.11.3 Research and development**

Research and development is required to increase understanding of the service (identify potential hazards), validate that existing and proposed processes will successfully control hazards and to design new equipment.

Many providers undertake various research and development activities as part of their normal business, such as investigative studies and attending conferences to maintain awareness of emerging technologies and industry best practice.

The level of research and development undertaken will differ significantly between providers, and should be appropriate to the size and complexity of the service. Providers should maintain records of all research and development activities.

Investigative research and development activities may include:

- catchment surveys—used to identify activities that may affect drinking water quality such as pesticide use
- baseline source water monitoring—used to identify potential issues such as high naturally occurring fluoride and exploring seasonal or event driven variations in water quality
- attending conferences and reading journal articles—used to maintain awareness of emerging technologies and industry best practice
- planning studies—used to investigate ways to optimise or improve the system performance. Planning studies may also be used to validate the selection of potential new infrastructure by documenting expert judgement and referencing published technical literature.

To meet this recommendation, the plan should document what research and development activities are currently undertaken and ensure that the plan allows for any ongoing research and development activities that are required to support continual improvement.

### **3.11.4 Review and continual improvement**

#### **Review by senior executive**

Providers should regularly review the activities relating to the service to improve operational processes and drinking water quality management. The review should ensure any changes to the internal (that is, activities of the organisation or outcomes of incidents) and external (that is, advances in science and technology or changes to legislation) environment are reflected in the operations of the service.

To meet this recommendation the plan should document the procedure for undertaking reviews of the effectiveness of the drinking water quality management system by a senior executive and evaluate the needs for change (that is, update policy, the plan, operational procedures).

## 4. Approval of the plan

### 4.1 Applying for approval of the plan

Each provider must apply to the regulator for approval of the plan. A copy of the plan must be submitted with an application for approval in accordance with section 95(2) of the Act<sup>19</sup>.

An application form for the plan is available on the department's website at <[www.derm.qld.gov.au](http://www.derm.qld.gov.au)>.

### 4.2 Assessment process for the plan

#### 4.2.1 Regulator's considerations when making a decision about the plan

In accordance with section 98 of the Act, when considering the plan the regulator must have regard to the following:

- (a) the plan and any additional information about the plan given to the regulator under section 96 of the Act
- (b) this guideline prepared by the regulator
- (c) any advice obtained by the regulator under section 97 of the Act
- (d) the water quality criteria for drinking water.

#### 4.2.2 Request for additional information

The regulator must be satisfied that the plan is adequate to protect public health. In accordance with section 96 of the Act, the regulator may, by notice given to the provider, require the provider to give additional information about the plan, including, for example, information about arrangements relating to the supply of water to or from the provider's service. A requirement to give additional information under section 96 of the Act is an 'information requirement'.

If the provider fails, without reasonable excuse, to comply with the requirement within the reasonable period stated in the notice, the application is taken to be withdrawn.

In addition to requesting the provider to give additional information, the regulator may also obtain advice from an advisory council or any other entity the regulator considers appropriate, before making a decision on the application in accordance with section 97 of the Act.

#### 4.2.3 Timeframes for decisions

In accordance with section 98 of the Act, the regulator must consider each application and decide to approve, with or without conditions, or refuse to approve, the plan:

- if an information requirement is not made in relation to the plan—within three months of receiving the plan
- if an information requirement is made in relation to the plan—within three months of the requirement being complied with.

---

<sup>19</sup> Section 95(2)(b) of the Act states that the application must be accompanied by the fee prescribed under a regulation. However, currently there is no prescribed fee for an application for the plan.

#### 4.2.4 Regulator’s decisions

After considering the plan, the regulator may approve the plan, with or without conditions, or refuse to approve the plan. The information the regulator must include in the notice of the decision or an information notice for the decision is given in accordance with section 99 of the Act and is shown below in Table 3.

**Table 3: Regulator’s decisions**

Decision	Factors included in the decision
Approve the plan without conditions	<p>The regulator must give the provider a notice of the decision.</p> <p>The notice of the decision must state:</p> <ul style="list-style-type: none"> <li>• the intervals at which:                             <ul style="list-style-type: none"> <li>▪ regular reviews of the approved plan must be conducted (not less than one year)</li> <li>▪ regular audits of the approved plan must be conducted (not less than two years).</li> </ul> </li> </ul>
Approve the plan with conditions	<p>The regulator must give the provider an information notice for the decision.</p> <p>The information notice for the decision must state:</p> <ul style="list-style-type: none"> <li>• the conditions of the approval</li> <li>• the intervals at which:                             <ul style="list-style-type: none"> <li>▪ regular reviews of the approved plan must be conducted (not less than one year)</li> <li>▪ regular audits of the approved plan must be conducted (not less than two years).</li> </ul> </li> </ul>
Refuse to approve the plan	<p>The regulator must give the provider an information notice for the decision.</p>

Section 99(1) of the Act states that, within 10 business days of deciding the application, the regulator must give the provider either the notice of the decision or the information notice for the decision.

#### 4.3 Approval of the plan

Approval is based on submission of the plan, completeness of the plan in addressing the criteria and the adequacy of the plan in appropriately managing the risks that have been identified. It involves a detailed review of the content and practicality of the plan in protecting public health.

An approval of the plan does not imply approval of supporting documentation accompanying the plan. That is, for example, the provider may reference a document (for example, mains breaks repairs procedures) in the plan to demonstrate how the criteria has been met. Similarly, the regulator in considering the provider’s plan may request a copy of the mains breaks repairs procedures to cite the specific reference as it relates to the criteria. The referencing of the mains breaks repairs procedures in the plan or the review of the specific section in mains breaks repairs procedures does not imply that the mains breaks repairs procedures (and its contents in its entirety) has been approved by the regulator as part of the plan approval. The provider remains responsible for ensuring appropriate procedures are in place for the service to protect public health.

#### 4.4 Conditions that can be placed on the plan

In accordance with section 99(2)(a) of the Act, the regulator can approve the plan with conditions. The types of conditions that can be placed on the plan include, for example:

- reporting drinking water quality incidents
- progress on a risk management improvement program (i.e. status report on their measures and actions)

- timing of particular actions, measures etc (i.e. bring forward a measure identified in the risk management improvement program)
- specific requirements (i.e. provide required information by a certain timeframe)
- conditions as deemed necessary by the regulator to protect public health.

## 4.5 Augmenting a drinking water supply with recycled water

The Act also deals with matters relating to recycled water aimed at protecting public health. For providers generally, an approved drinking water quality management plan must be in place by 1 July 2011, 2012 and 2013 for large, medium and small providers respectively. However, where a drinking water supply is augmented by recycled water, these arrangements do not apply.

Section 207 of the Act requires that before a recycled water management plan for a scheme that proposes to supply recycled water to augment a supply of drinking water is approved, there must be an approved drinking water quality management plan covering the water storage that will receive the recycled water. This means that the regulator will not approve a recycled water management plan for a recycled water scheme that proposes to supply recycled water to augment a supply of drinking water unless there is an approved drinking water quality management plan.

Where recycled water is proposed to be supplied under the recycled water scheme to augment a supply of drinking water, the complete water system (that is, from the source of recycled water to its addition to the drinking water supply), and ultimately the quality of water supplied to the customer (that is, from the drinking water supply to reticulation) should be covered by the combination of the drinking water quality management plan and the recycled water management plan.

The drinking water quality management plan that is developed for the receiving water storage and the water treatment plant(s) must meet all the requirements of the Act.

## 4.6 Appealing the decision

If the plan is refused by the regulator, or the provider disagrees with the conditions stated on the information notice for the decision, the applicant may appeal the decision.

Refer to Chapter 7, parts 1, 2 and 3 of the Act for further details about internal reviews and appeals of the regulator's decision.

## 4.7 Amending the approved plan

To retain the currency of the plan by ensuring continued compliance with the Act, the approved plan may require amendment. Amendments to the plan may be initiated:

- by a provider under section 100 of the Act

If the provider proposes to amend the plan they must apply<sup>20</sup> to the regulator for approval of the proposed amended plan.

- by the regulator under section 101 of the Act

The regulator may require a provider to amend the plan if the regulator is satisfied that the amendment is required to protect public health.

Before requiring the provider to amend the plan, the regulator must give the provider a show cause notice about the proposed amendment. After considering all properly made submissions about the proposed amendment, the regulator can decide whether the proposed amendment should or should not be made. If, after considering all properly made submissions, the regulator decides that the proposed amendment should be made, the regulator must give the provider a notice and an information notice for the decision in accordance with section 101(3) of the Act.

---

<sup>20</sup> Sections 95(2) and (3) and 96 to 99 of the Act apply to the application. That is, the same procedure that applies to the application for approval of the Plan applies to the application for amendment of the plan.

If the regulator is satisfied with the way the plan has been amended, the plan will then be taken to be the approved plan and the regulator must give the provider a notice stating that the plan as amended is taken to be the approved plan. The amended plan will take effect from the day the notice is given to the provider.

If, after considering all properly made submissions, the regulator decides that the proposed amendment should not be made, the regulator must give the provider a notice that the plan need not be amended.

## **4.8 Duration of the approved plan**

The plan does not have an expiry date however it should be a living document and updated in line with any changes to the external and internal operating environment.

A provider will be required to undertake a regular review (under section 106 of the Act) and regular audit (under section 108 of the Act) of the plan<sup>21</sup> at intervals stated by the regulator. The outcomes of the regular review of the plan may require an amendment to the plan (see guideline section 4.6). These outcomes will also need to be stated in the annual report<sup>22</sup> prepared by the provider for the service.

## **4.9 Operating under the approved plan**

### **4.9.1 Compliance with the conditions of the plan**

The provider must have an approved plan in place for the service. The provider is responsible for ensuring compliance with the approved plan and any conditions set by the regulator. Failure to comply with the plan or the conditions of the plan is an offence under section 93 of the Act.

### **4.9.2 Noncompliance with water quality criteria**

Under the approved plan, the provider must inform the regulator if the provider becomes aware that the quality of water supplied from the provider's service does not comply with the water quality criteria relating to the service.

In accordance with section 102 of the Act, unless the provider has a reasonable excuse, the provider must:

- immediately inform the regulator of the noncompliance with the water quality criteria and the circumstances that gave rise to the noncompliance
- give the regulator notice, in an approved form, of:
  - the noncompliance and the circumstances that gave rise to the noncompliance
  - any action taken or to be taken, by the provider to correct the noncompliance
  - the measures the provider will take to prevent the noncompliance in the future.

---

<sup>21</sup> A service provider must arrange for regular audit and compliance with the plan.

<sup>22</sup> The Drinking Water Quality Management Plan Annual Reporting Guideline is being developed and will be made available when approved.

## 5. Annual reporting, reviews and audits of the plan

Annual reporting, reviews and audits of the plan are requirements under the Act. The frequency of reviews and audits will be specified at the time of plan approval.

### 5.1 Annual reporting

In accordance with section 141 of the Act, a provider is required to prepare an annual report for each financial year after a financial year in which the plan is approved. The annual report may be prepared by the provider in combination with other reports required under section 141 of the Act. The provider must give a copy of the annual report to the regulator within 120 business days after the end of the financial year to which it relates.

Section 142 of the Act outlines the contents that must be included in the annual report for the plan.

Under section 142(2) of the Act, an annual report for the plan must, for example, contain a summary of the provider's compliance with the plan in relation to the water quality criteria for drinking water. This summary may contain the corrective and preventive actions taken by the provider in complying with the water quality criteria for the plan.

In accordance with section 575 of the Act, a provider must keep a copy of the annual report for inspection and purchase by the public.

### 5.2 Reviews and audits

Section 106(4) of the Act requires a provider to regularly review the provider's plan in accordance with the timeframes stated in a notice of the decision or an information notice for the decision given by the regulator under section 99 of the Act.

#### 5.2.1 Reviews

In accordance with section 106(5) of the Act, the purpose of the review of the plan is to ensure that the plan remains relevant to the operation of the service provided by the provider. The annual report for the plan must contain the outcome of any review of the plan and how the provider has addressed matters raised in the review.

#### 5.2.2 Audits

##### Audit reports

Section 108 of the Act states a provider is required to arrange for regular audit reports on the plan and compliance with the plan. The purpose of the regular audit report is:

- (a) to verify the accuracy of the monitoring and performance data provided to the regulator under the plan
- (b) to assess the provider's compliance with the plan
- (c) to assess the relevance of the plan in relation to the provider's service.

The annual report for the plan must contain a summary of the findings of, and any recommendations stated in, a regular audit report.

The regular audit report must be prepared by a person who is certified under the Drinking Water-Quality Management System Auditor Certification Scheme, or has a qualification the regulator is satisfied is at least equivalent to the Drinking Water-Quality Management System Auditor Certification Scheme. The report must be given to the regulator within 30 business days after its completion and made available for inspection and purchase. The regular audit report must be accompanied by a statutory declaration by the provider and the auditor.

##### Spot audits

Section 110 of the Act allows the regulator to arrange for a spot audit report to be prepared about the provider's plan in the following circumstances:

- (a) if the regulator is satisfied, or reasonably believes:
  - (i) a provider is not complying with the plan

or

- (ii) a provider's plan is no longer adequate for the provider's registered services
  - or
- (b) a provider does not:
  - (i) have an audit report prepared under section 108 of the Act
    - or
  - (ii) give the regulator a copy of an audit report under section 108 of the Act.

The regulator may only arrange for a spot audit if the regulator has given the provider a show cause notice in accordance with section 463 of the Act.

The spot audit for the plan must be prepared by a person who is certified under the Drinking Water-Quality Management System Auditor Certification Scheme, or has a qualification the regulator is satisfied is at least equivalent to the Drinking Water-Quality Management System Auditor Certification Scheme.

The spot audit report submitted to the regulator must be accompanied by a statutory declaration by the auditor. The regulator must give the provider a copy of the report within 30 business days after its completion.

If the report states the plan is inadequate in a material particular or the provider has not properly carried out the plan, the regulator must give the provider an information notice requiring the provider, within the reasonable period stated in the notice to either rectify the inadequacy or to properly carry out the plan.

The regulator may recover from the provider an amount equal to the cost of completing the report.

## 6. Glossary

**Note: This guideline glossary contains terms taken from the Act and terms taken from various water industry sources. The provider should refer to the Act for the meaning of the terms. However, terms referred to in this guideline are provided below for your convenience.**

Term	Meaning
ADWG	The Australian Drinking Water Guidelines incorporate the Framework for the Management of Drinking Water Quality based on the 12 elements and provides guidance on what constitutes good quality drinking water.
Conditions	Set by the regulator*.
Consequence	Consequence of a hazardous event occurring (for example, catastrophic, major, moderate, minor, or insignificant).
Control measure (preventive measure)	Any action or activity that can be used to prevent, eliminate or reduce a hazard to an acceptable level.
Corrective actions	Corrective actions are those taken immediately to prevent hazards from reaching end users for example, actions taken following noncompliance with water quality criteria.
Critical Control Point (CCP)	A point, step or procedure at which control can be applied and which is essential to prevent or eliminate a hazard or reduce it to an acceptable level.
Department	Department of Environment and Resource Management.
Distribution system	Means the infrastructure for: <ul style="list-style-type: none"> <li>(a) the transmission of water</li> <li>or</li> <li>(b) the reticulation of water</li> <li>or</li> <li>(c) water treatment or recycling*.</li> </ul>
Drinking water	Means water, for human consumption, intended primarily as water for drinking, whether or not the water is used for other purposes. Drinking water does not include: <ul style="list-style-type: none"> <li>(a) water that is food as defined under the <i>Food Act 2006</i></li> <li>or</li> <li>(b) water taken or supplied for domestic purposes under the Water Act*.</li> </ul>
Drinking Water Quality Management Plan (the plan)	Means a plan about the storage, treatment, transmission or reticulation of water for drinking by a drinking water service provider*.
Drinking Water Quality Management Plan Auditing and Review Guidelines	Guidelines issued by the regulator under section 571(o) of the Act are yet to be developed.

---

\* See Schedule 3 of the Act.

Term	Meaning
Drinking Water Quality Management Plan Annual Reporting Guidelines	Guidelines issued by the regulator under section 571(1) of the Act are yet to be developed.
Drinking water scheme	Infrastructure owned by a provider for single or multiple combinations of the individual components of treatment, transmission, or reticulation of drinking water supply, or the storage of recycled water to augment a drinking water supply. Refer to the Water Quality and Reporting Guideline for a Drinking Water Service for further information.
Drinking water service	Means a water service that is: <ul style="list-style-type: none"> <li>(a) the treatment, transmission or reticulation of water for supply as drinking water or</li> <li>(b) water collection in a water storage, if the water in the storage:               <ul style="list-style-type: none"> <li>(i) includes recycled water and</li> <li>(ii) is used to augment a drinking water supply*.</li> </ul> </li> </ul>
Drinking water service provider	Means a water service provider for a drinking water service*.
Excursion including operational excursion	When a parameter goes outside identified limits. These limits may include alert levels, critical limits or water quality criteria.
HACCP	Hazard Analysis and Critical Control Point is an internationally recognised risk management system used extensively in the food industry.
Hazard	A biological, chemical, physical or radiological agent that has the potential to cause harm (contaminant).
Hazardous event	An incident or situation that can lead to the presence of a hazard (what can happen and how).
Large service provider	<ul style="list-style-type: none"> <li>(a) a service provider primarily providing bulk water services or</li> <li>(b) for a retail water service or sewerage service—a service provider with more than 25 000 connections to a registered service or</li> <li>(c) for a drinking water service that is the reticulation of water and is not a retail water service—a service provider with more than 25 000 connections to a registered service or</li> <li>(d) for an irrigation service—a service provider with:           <ul style="list-style-type: none"> <li>(i) more than 500 users and</li> <li>(ii) a volume throughput, in any of the last five financial years, of more than 10 000ML*.</li> </ul> </li> </ul>

---

\* See Schedule 3 of the Act.

<b>Term</b>	<b>Meaning</b>
Likelihood	Likelihood of hazard (for example, almost certain, likely, possible, unlikely, rare).
Maximum risk	Assumes that no preventive measures are in place.
Medium service provider	<p>(a) for a retail water service or sewerage service—a service provider with more than 1000 but not more than 25 000 connections to a registered service; or</p> <p>(b) for a drinking water service that is the reticulation of water and is not a retail water service—a service provider with more than 1000 but not more than 25 000 connections to a registered service</p> <p>or</p> <p>(c) for an irrigation service—a service provider with:</p> <p>(i) more than 100 but not more than 500 users</p> <p>and</p> <p>(ii) a volume throughput, in any of the last five financial years, of more than 10 000ML*.</p>
Operational monitoring	The act of conducting a planned sequence of observations or measurements that ensure that the system, including critical control points, is operating within performance limits in real time.
PAC	Powdered activated carbon.
Preventive measures/actions	Any action or activity that can be used to prevent, eliminate or reduce a hazard to an acceptable level.
Providers that store or treat source water containing recycled water intended to augment a drinking water supply	<p>If the drinking water service carried out by the provider is:</p> <p>(a) water collection in a water storage, if the water in the storage:</p> <p>(i) includes recycled water;</p> <p>and</p> <p>(ii) is used to augment a drinking water supply</p> <p>or</p> <p>(b) the treatment of water intended for drinking that is sourced from a water storage, or water released from a water storage, mentioned in paragraph (a).</p>
Recycled water	In the context of this guideline, recycled water refers to recycled water that is used to augment a drinking water supply.
Regulator	The chief executive of the department is the regulator under the Act. The chief executive of the department, as the regulator, has delegated certain powers under the Act to the officers of the Office of the Water Supply Regulator*.
Residual risk	Includes the mitigating effects of existing preventive measures.
Risk	Risk is defined as the likelihood of identified hazards causing harm in exposed populations in a specified timeframe, including the severity of the consequences (i.e. risk = likelihood x consequence).
Service provider	Means a water service provider or a sewerage service provider*
Small service provider	(a) for a retail water service or sewerage service—a service provider with 1000 or less connections to a registered service

\* See Schedule 3 of the Act.

Term	Meaning
	<p>or</p> <p>(b) for a drinking water service that is the reticulation of water and is not a retail water service—a service provider with 1000 or less connections to a registered service</p> <p>or</p> <p>(c) for an irrigation service—a service provider with:</p> <p>(i) 100 or less users</p> <p>or</p> <p>(ii) a volume throughput, in any of the last five financial years, of 10 000ML or less</p> <p>or</p> <p>(d) for a water service other than a water service mentioned in paragraph (a), (b) or (c), a service provider:</p> <p>(i) with not more than 500 customers</p> <p>and</p> <p>(ii) that mainly provides drainage services or water for domestic purposes or for watering stock*.</p>
Spot audit	Means an audit conducted under section 110 of the Act*.
Uncertainty	<p>Relates to the level of confidence that is placed in the risk assessment and arises from issues such as:</p> <p>(a) lack of complete knowledge; or</p> <p>(b) variability of information.</p>
Verification monitoring	Used to confirm product quality at the point of supply, compliance with water quality criteria and to identify deficiencies in existing preventative/control measures. It is an assessment of the performance of the scheme, and unlike operational monitoring, it does not occur in real time.
Water quality criteria	<p>for drinking water, means all of the following:</p> <p>(a) the standards for the quality of drinking water prescribed in a regulation under the Public Health Act</p> <p>(b) the criteria stated in a guideline, if any, made by the regulator about the quality of drinking water</p> <p>(c) the criteria for the quality of drinking water stated in a condition applying to a drinking water quality management plan.</p>
Water service provider	Means a person registered under Chapter 2, part 3 as a service provider for a water service*.

---

\* See Schedule 3 of the Act.

**List of Figures**

Figure 1: The Ecological Risk Assessment (ERA) framework..... 9

Figure 2: Ecological responses occur in reaction to the physical and chemical conditions experienced by biota, not directly to altered flow regimes. Altered flows influence ecology by interacting with various other properties of the setting to modify the conditions the biota experience. To understand ecological responses to flow modification one must first understand the relationships between physical/chemical conditions and the ecological response, and second, understand the relationship between flow and the provision of these conditions. Stressors other than altered flow may also influence the response, so the effectiveness of flow regime restoration or protection can not be judged directly by the occurrence or intensity of a response. Rather, it must be judged by evaluating the provision of the flow-related conditions necessary for the response to occur. .... 11

Figure 3: For an ecological value (e.g. Rainbowfish persistence) a breakdown of the criteria (abundance and distribution) and sub-criteria (number, age class, occupancy) that contribute to its value indicates aspects that need to be considered when assessing how flow management provides for that value. .... 14

DRAFT

## 1. Executive summary

Ecological risk assessment was undertaken to examine the implications of flow regime changes from water resource development on the long term viability of ecological assets. Ecological assets with critical links to flow were selected as indicators of the ecosystem, and assets with links to a range of flow classes were assessed (see Table 1).

The approach was based on methods developed for population viability analysis and was formalised through the construction of conceptual models, knowledge acquisition, and the construction of semi-quantitative and quantitative population models. A variety of data sources were used in the development of risk assessment models, including literature reviews, monitoring data and expert advice.

Because of the unique and specific requirements of ecological assets, the assessment was tailored to each asset based on the available information. In general terms the assessment considered the potential risk from flow management to the viability of the asset in question, based on the known flow requirements of the asset that are required for long term integrity. It is important to note that assessment of risk was only for flow related risk and did not include risk from other factors, such as the effects of weirs and barriers on connectivity.

The assessment firstly considered the opportunities provided by flow management for responses of individual organisms at particular places and times; and secondly the frequency and sequence of opportunities determines population responses, and thus the viability of values. In calculating potential risk to the asset from flow management, aspects of both likelihood and consequence were considered.

A total of 12 assets were assessed at up to 14 locations around the Fitzroy Basin (Table 1). The critical flow requirements of five assets were linked to no flow/low flow conditions, and included *Ambassis agassizii* (Glassfish), *Mogurnda adspersa* (Purple spotted gudgeon), *Melanotaenia splendida splendida* (Rainbowfish), waterholes as refugia and riffles as habitats. Two assets were linked to medium to high flows, including flow spawning fish (i.e. *Macquaria ambigua orientalis* (Fitzroy golden perch)) and riparian vegetation communities (i.e. *Eucalyptus coolabah*). High to flood flow assets included wetlands and floodplain lagoons and the estuarine/marine species *Lates calcarifer* (Barramundi), *Penaeus merguensis* (Banana prawns), offshore reef fisheries and *Polydactylus macrochir* (King threadfin salmon).

Five assets were identified at low risk, of which four were low flow assets. The stable flow conditions necessary for low flow spawning fish (which included glassfish, purple spotted gudgeons and rainbowfish) were similar between flow scenarios, with some sites downstream of water infrastructure providing more spawning opportunity. Waterholes were modelled at low risk, with large waterhole size and flow supplementation (from upstream storages) contributing to the low risk. Barramundi growth was also modelled at low risk.

All remaining assets were identified at higher risk; however the degree of potential risk varied both within and between asset groups. The only low flow asset potentially at higher risk was riffles as habitat where an increase in dry periods was observed. Sites upstream of the water supply scheme remained generally unchanged (e.g. Taroom and Baroondah), whilst risk in the supplemented water supply schemes increased with downstream distance. Risk also increased at sites affected by the proposed Nathan Dam.

Both the medium to high flow assets, flow spawning fish and riparian vegetation communities, were modelled at higher risk. The findings of the Fitzroy golden perch Bayesian modelling suggested that, under the current development scenario, the population is mostly affected in the middle sections of the catchment. Future developments represent a greater risk, particularly in the middle to lower Dawson River where the impacts of the proposed Nathan Dam were realised.

Riparian vegetation communities, of which Coolabahs were the indicator species, experienced less flooding frequency, with sites directly downstream of major water infrastructure the most affected. Weirs were found to have very little influence on the flooding of riparian vegetation communities.

Wetland flooding downstream of major water infrastructure was also modelled to occur less frequently, with spells between flooding increasing under the development scenarios.

Notwithstanding these results, compensatory environmental flows may not be practical, if at all possible, for riparian vegetation communities and wetlands. Major flow events provide the only means of flooding as discharge capacities of the major infrastructure, including Fairbairn Dam, are not large enough to provide the necessary flooding flows.

Barramundi, king threadfin and offshore reef fisheries were all modelled to be at potentially higher risk under both development scenarios. Reductions in wet season flows during periods of naturally low flow were the primary cause for the increased risk profiles, with each asset having between 2 to 4 high risk periods over the 107 modelled sequences. In most instances, these high risk periods were not present in the pre-development scenario where the sequences were interrupted by years where flows provided the necessary recruitment conditions. During extended periods of low flow, low storage volumes and a high demand for water harvesting is expected, which would reduce the volume of water reaching the estuarine/marine systems. Given that these flows are very important for securing existing water entitlements, it is not expected that compensatory environmental flows during these low flow periods would be possible.

**Table 1: Summary of ecological assets potential risk trajectory under the development cases. Upward arrow represents an increase in risk; downward arrow represents a decrease in risk; circles represent no change in risk profile.**

Location		Low flow assets					Medium-High flow assets		High-flood flow assets						
		Glassfish	Purple spotted gudgeon	Rainbowfish	Waterholes	Riffles	Flow spawning fish	Riparian veg.	Wetlands	Barra (YCS)	Barra (growth)	Barr (recruits)	Banana prawns	Offshore reef fisheries	King salmon

These assessments also highlighted that further research is required to improve our understanding of the ecological risk through water resource planning. These included:

- Floodplain Riparian Vegetation Communities and wetlands where it was recommend that future studies be undertaken which assesses whether changes in flooding frequency impact on riparian communities and wetlands
- Barramundi, offshore reef fisheries and Threadfin salmon risk must be considered in a wider context, as their persistence is influenced by a variety of activities, including over fishing and habitat alterations. The increased risk to recruitment also needs to be assessed in terms of its potential impact on fisheries industry (this is also pertinent to Banana prawn production).
- Risk to the riffle community remains unknown and the consequence of these changes require further investigation.
- Risk to unsupplemented waterholes was not assessed in detail and requires further research
- The population status of flow spawning fish needs confirmation and management of connectivity of all parts of the basin's river network may require a high priority for long-term population management

In addition to further research on assets, the ecological modelling method requires improvement to include:

- The effects of barriers to longitudinal connectivity, as risk may be underestimated if recolonisation processes are impacted by barriers to dispersal.
- Details about how local populations rebound from adversity (or even local extinction), particularly as many high risk assets had long periods (up to 16 years) without receiving their critical water requirements.
- Asset thresholds of concern are currently binary (i.e. pass or fail) whereas current research suggests that these functions follow a more sigmoidal curve. Ongoing research is required to develop more rigorous population models to derive these functions.
- A more transparent process of linking the asset risk back to the values associated with the ecological outcome.

## 2. Introduction

### 2.1 Background

#### Overview

WRPs are subordinate legislation under the Water Act 2000, and are reviewed and replaced every 10 years in accordance with the Statutory Instruments Act 1992 and the Water Act 2000. The Fitzroy WRP 1999 will expire on the 1st September 2010 and must be replaced by a new WRP prior to this date. This report forms one part of the technical assessments undertaken to support the preparation of a water resource plan (WRP) to replace the Water Resource (Fitzroy Basin) Plan 1999 (Fitzroy WRP 1999).

The Fitzroy WRP 1999 was finalised in December 1999 as the first basin-wide plan in Queensland. It was written in response to the Council of Australian Governments' (COAG) 1994 Water Reform Framework Agreement to address a number of water allocation and management issues. The plan initially applied only to water in a watercourse, lake or spring (other than springs connected to artesian water, directly or via subartesian water). In 2005, it was amended by the Water Resource (Fitzroy Basin) Amendment Plan (No. 1) 2005 to include overland flows.

A Technical Advisory Panel (or TAP) was appointed by the department during the development of the Fitzroy WRP 1999 to provide advice on:

- the likely environmental flow requirements of river systems associated with the Fitzroy Basin;
- possible environmental flow management scenarios that might address some of these requirements; and
- the potential ecological implications associated with various combinations of possible future development scenarios and/or environmental flow management scenarios.

The TAP consisted of a range of environmental and other technical specialists, who were considered experts in their fields and had extensive local knowledge of the Fitzroy basin. Assessments made by the panel were expert opinion, based on their experience and comparison to sites under similar water resource development pressures within the catchment or in other catchments. This approach fulfilled the requirements under the 'National Principles for the Provision of Water for Ecosystems' for recommendations on environmental flows to be based on the best scientific information available (ARMCANZ and ANZECC 1996).

The approach of using expert panels for determining environmental flow requirements has been common throughout Australia in the 1990's and into the 21st century. Cottingham et al. (2001) reported that:

*“One of the main attractions of Scientific Panels is that they can make decisions or develop recommendations in situations when information on flow–ecology relationships is limited. However, the lack of quantitative information — in particular, information on relationships*

*between flow and ecology or geomorphology — is also considered to be a common limitation to the Scientific Panel method and similar ‘holistic’ frameworks for determining environmental flows (Arthington 1998).”*

The requirement for the ‘best scientific information available’ to determine the duration, frequency, size and timing of water flows is captured in the Water Act (2000), however the Act does not specify how this requirement is to met. While TAPs are still being used by the department to develop new water resource plans, a new approach has been trialled for the review and replacement of the Fitzroy WRP 1999.

This approach involved the department undertaking an assessment of the effectiveness of the current WRP and its implementation through the ROP, based on monitoring and assessment undertaken by the department and others since the development of the first plan. This assessment was then peer reviewed by three eminent scientists for its quality and comprehensiveness, referred to as a Scientific Review Process (or SRP).

Since the development of the first plan, biologists have been employed by the department to monitor the effectiveness of the current flow management strategies in each WRP, as indicated by the requirements of selected ecological assets with critical links to flow. The information gathered from this monitoring program, and other monitoring programs and research undertaken in the catchment now represents the best scientific information available. As such, this information has been drawn together and forms the scientific basis for this report. In addition, the approach used in this report has been peer reviewed by Mark Burgman, Australian Centre of Excellence for Risk Analysis, and the science and assumptions underpinning the assessment has been reviewed by numerous experts at various stages in the process (more information is provided on this later in the report).

The use of data collected as part of a targeted monitoring program to assess the effectiveness of the plan, and review of this assessment by external experts builds on the previous expert panel approach. The rigour of the assessment produced is improved by inclusion of highly relevant and informative data and assessments, and the capture of external scientific information from experts is maintained as part of the process.

### **Ecological Risk Assessment**

An Ecological Risk Assessment (ERA) framework has been used to make an assessment of the effectiveness of the current plan in meeting its stated ecological outcome, using ecosystem values or ecological assets as indicators of the outcome. This approach involves assessing the implications of current and future water management scenarios for the long term viability of ecosystems in the WRP area. A risk assessment approach enables comparison of relative risk from multiple flow management scenarios, including the predevelopment scenario (representing the natural risk to the ecosystem).

Knowledge of the relative impact of flow management on ecosystem outcomes is vital to making informed decisions regarding flow management strategies. Because the risk assessment approach used in this report deliberately isolates the impact of flow management from all other factors impacting ecosystems, the assessment is more informative and targeted to the assessment of flow management strategies than ecosystem condition information alone. The risk assessment considers the impact of flow management on persistence and long term viability of the assets in the WRP area; therefore it captures risk to the long term condition of the ecosystem, in line with the longer timeframe in which the ecological outcomes of the plan are designed to be achieved.

Importantly, the risk assessment approach applied for the Fitzroy WRP environmental assessment considers both likelihood (probability of impact from flow management) and consequence (impact on asset) aspects where possible in making a risk assessment. Where insufficient information was available for the asset to complete an assessment of consequence, only likelihood has been reported and this can be considered a 'hazard' assessment rather than a risk assessment. Where sufficient information was available for both aspects, risk has been reported.

Risk is reported over the timeframe of the assessment period (approximately 100 years) and considers the effect of simultaneous failures in the population over space and time. Therefore there is more realism in the assessment than the qualitative risk assessment undertaken in the asset selection process, and as such this has been termed a 'medium intensity' risk assessment (see Figure 1). Still more complexity and realism is possible by developing a population model, and this has been completed for only one asset, the Fitzroy golden perch. This is a highly resource intensive exercise and as such is termed a 'high intensity' risk assessment (Figure 1).

The advantages of the risk assessment approach presented in this report include that it is much more quantitative than previous assessments, it can be repeated if new information becomes available, it makes use of the best available science which may be data or expert opinion, and the results obtained are comparable for each scenario. Documentation of assumptions and peer review of the assessment reduces the possibility of expert bias, provides transparency and allows validation of the approach and the science underpinning the assessment.

## **2.2 Objectives**

This technical report is the third in a series of technical reports that contribute to the ERA framework, and includes:

- Technical Report 1: Asset Selection Report Fitzroy WRP 1999 (Cockayne 2008) focuses on the selection and prioritisation of the specific ecological values (or assets) that have been used in the ERA.
- Technical Report 2: Summary of monitoring and findings from the Environmental Flows Assessment Program (2004 - 2008) (Espinosa and Cockayne 2009) documents the findings from the monitoring and research undertaken for a specific ecological asset

(Fitzroy Golden Perch) as part of the Environmental Flows Assessment Program (EFAP).

- Technical Report 4: Golden Perch Population Model - Using spatial population dynamics for assessing water resource development (Menke et al., 2009) demonstrates the application of Bayesian Networks to assess the risk, through space and time, to Golden Perch population viability under various flow management options.
- Technical Report 5: Hydrologic Deviation Analysis (Tom & Coysh, 2009) provides the hydrologic context to the risk analysis for the selected ecological assets.
- Technical Report 6: Assessment of the ecological intent behind the Fitzroy Basin Water Resource Plan and Resource Operation Plan Environmental Flow Management Strategies assessed whether the ecological intent behind the Fitzroy Basin WRP and ROP environmental flow management strategies were achieved.
- Technical Report 7: Summary of findings from the environmental assessment of the Fitzroy Basin WRP summarises the results of the above reports.

The objectives of the assessment in this report are to:

- Determine how the ecological assets critical water requirements are provided under the various IQQM scenarios
- Quantify risk posed to the ecological assets
- Identify nodes and periods where scenarios have biggest impact on asset risk
- Identify flows requiring protection under the WRP/ROP
- Develop ecological risk assessment method which can be assist the development and review of future WRP/ROP
- Provide direction to future monitoring activities

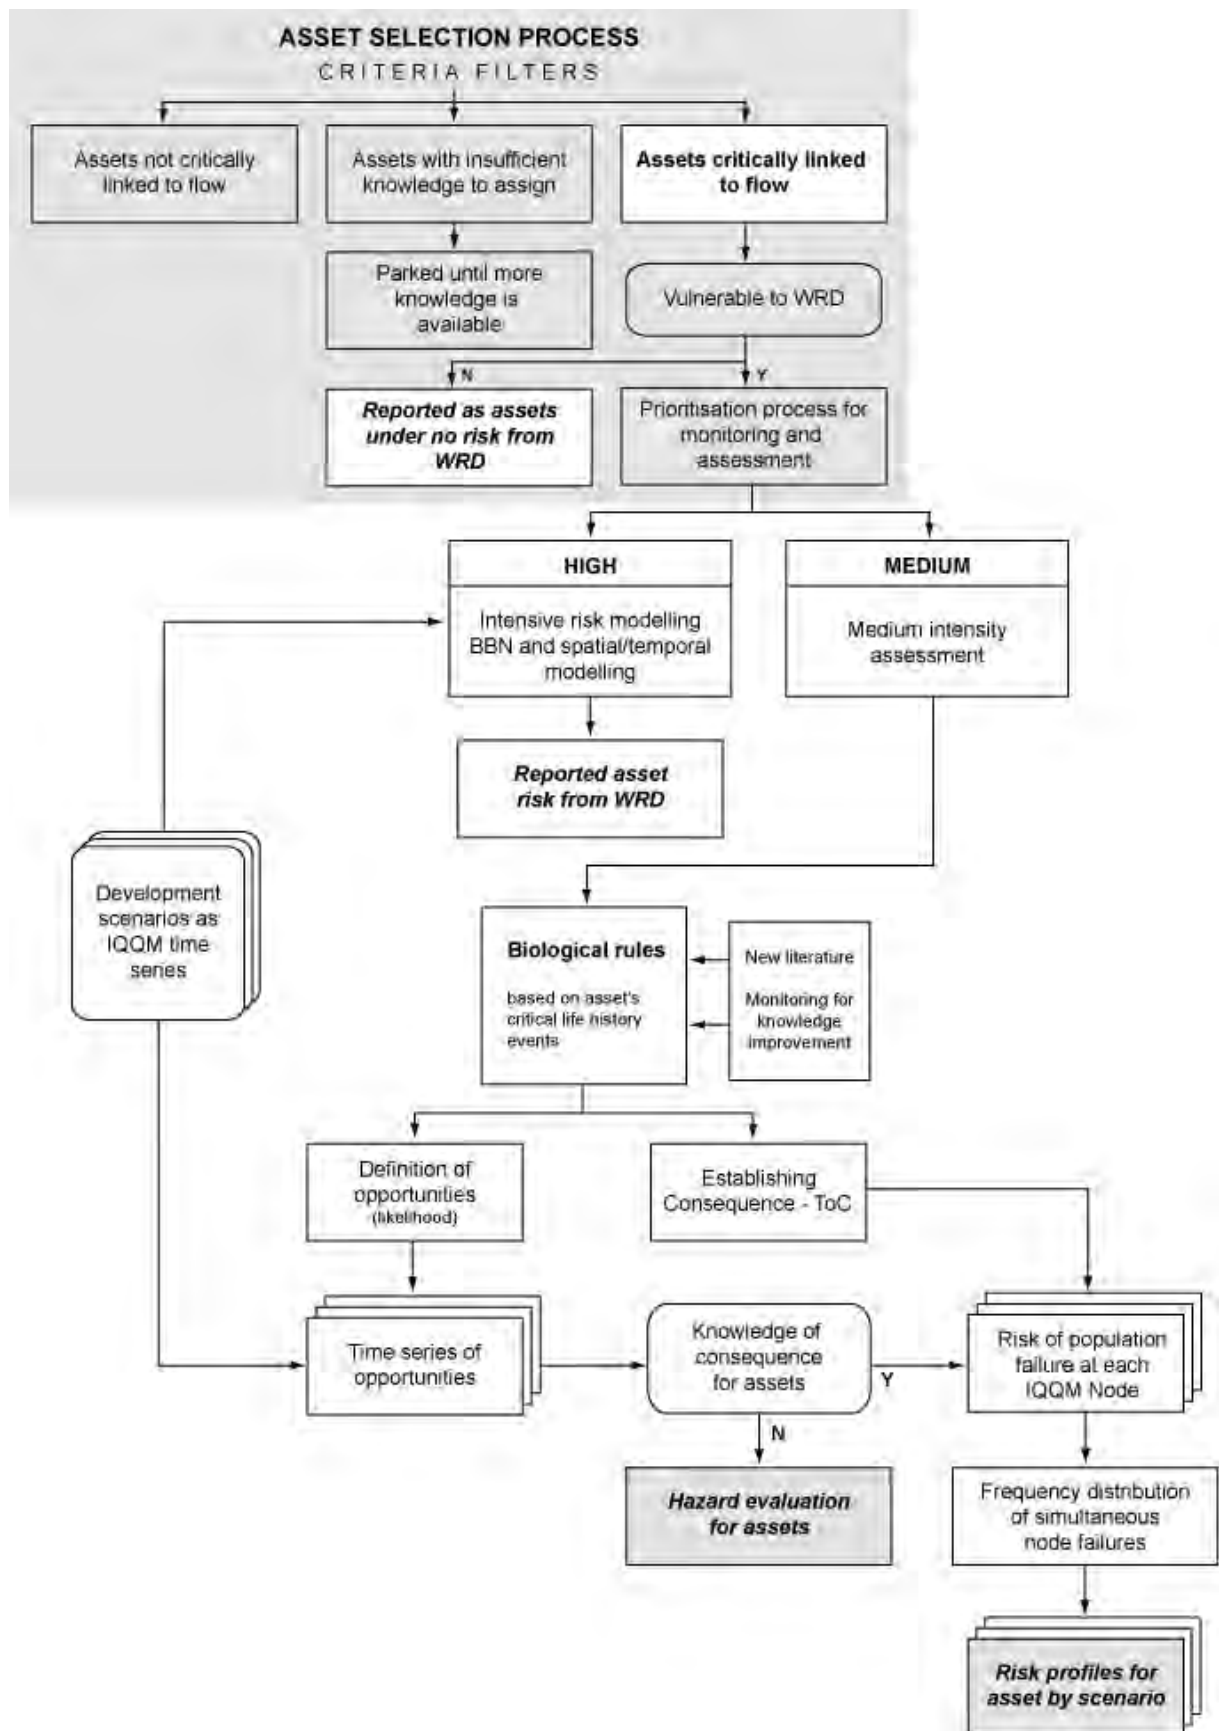

Figure 1: The Ecological Risk Assessment (ERA) framework

## **2.3 Rationale**

The quantification of ecological responses to altered flow regimes is typically compromised by both confounding stressors and by the complex nature of the relationships between flow and ecology. The setting is critical to understanding these relationships and in most cases direct relationships between flow regime change and ecological condition (i.e. ecological health) are not measurable. This is supported by the outcomes of two large-scale studies conducted by DERM in the Condamine-Balonne and Fitzroy River catchments (Marshall & Negus, 2003; Marshall et al 2003; Negus et al 2003; Condamine refs needed).

These two studies investigated the responses of multiple ecological condition indicators to gradients of flow alteration and both demonstrated that community and process based ecological condition indicators did not respond to flow change in a predictable way (Negus et al. 2004). Thus such an approach can not inform flow management decisions. This result is corroborated by a global literature review (Poff and Zimmerman, 2007) which concluded that general, quantitative patterns between flow alteration and ecological responses are not strongly evident.

The absence of predictable ecological responses to flow modification is, in part, due to the influences of confounding stressors (e.g. land use gradients often correlate with gradients of flow alteration), but fundamentally it is because biota do not experience or respond directly to hydrology. Rather, flow interacts with other features to produce physical, chemical and biological conditions which biota perceives and which elicit ecological responses (Figure 2). Fish, for example, do not perceive mean annual discharge, but they do perceive depth, velocity and water temperature and react to these in measurable and predictable ways.

So, in order to inform the management of flow regimes to achieve ecological outcomes, we must abandon the notion of seeking direct flow-ecology relationships and focus our attention on understanding what conditions elicit ecological responses and how flow interacts with other aspects of the local setting to provide these conditions. The interactions between particular responses and the conditions that trigger them should be general and transferable. In contrast, the provision of the necessary conditions that is created by the flow regime interacting with other influences is a function of setting and thus is not transferable.

Because responses are also influenced by stressors other than flow alteration, it does not necessarily follow that good flow management will necessarily elicit the intended ecological outcome. Consequently it is not possible to evaluate the effectiveness of flow management by measuring the occurrence or the intensity of ecological responses. Even if flow management is ideal the response may not occur because of another stressor. For this reason the ecological implications of flow management should be determined and assessed by evaluating the provision of the flow-related conditions required for the response.

In this assessment, we apply this logic using ERA to assess the risk to specific ecological values that are linked to ecological responses that rely upon critical flow-related conditions. Relative risk to the ecological values between the predevelopment flow regime (as a reference) and the flow regimes generated by different management options are used as indices of ecological outcomes from management. This approach accounts for both the potential influence of confounding stressors and the complex relationships between flow, setting and ecology.

**Figure 2: Ecological responses occur in reaction to the physical and chemical conditions experienced by biota, not directly to altered flow regimes. Altered flows influence ecology by interacting with various other properties of the setting to modify the conditions the biota experience. To understand ecological responses to flow modification one must first understand the relationships between physical/chemical conditions and the ecological response, and second, understand the relationship between flow and the provision of these conditions. Stressors other than altered flow may also influence the response, so the effectiveness of flow regime restoration or protection can not be judged directly by the occurrence or intensity of a response. Rather, it must be judged by evaluating the provision of the flow-related conditions necessary for the response to occur.**

### **3. Methodology**

#### **3.1 A ‘medium intensity’ assessment of the risk flow management poses to asset viability**

The assessment approach described herein is termed ‘medium intensity’ to differentiate it from the high intensity method exemplified by the Fitzroy Golden Perch Bayesian population viability model (Menke et al 2009) and the low intensity risk assessment used to prioritise assets and identify those at no risk from flow management (Cockayne, 2008) (Figure 1- Medium intensity assessment). This approach is based on methods and ideas developed for population viability analysis and is formalised through the construction of conceptual models, knowledge acquisition, and the construction of semi-quantitative and quantitative population models. It recognises that in most cases there will be a paucity of information on the assets of interest and provides a framework for the clarification of assumptions and integration of knowledge from all available sources. The quantitative risk assessment is the most rigorous, requiring the highest data quality, and model building effort (see Menke et al 2009). This section describes the generic method applied to all assets. Specific details of its application to each individual asset are provided in sections of the report relating to the assets.

The starting point for this process is the selection of ecological assets (with their critical links to flow and the values they support) that have been identified by the asset selection process (Cockayne, 2008) as being of potential risk from flow management in the Fitzroy WRP area. It is important to recognise the general mechanisms by which flow management may influence these assets and their associated values (see Introduction). These are not direct relationships, but rather are two step processes whereby firstly flow management provides opportunities for the responses of individual organisms at particular places and times and secondly the frequency and sequence of opportunities determines population responses and thus the viability of values.

#### **3.2 Time series of opportunities**

Opportunities for individuals to respond depend upon provision of suitable environmental conditions for the response. These conditions can be considered as triggers and be defined by a set of biological rules (see Figure 1- Biological rules). For assessing the risk posed by flow management, these biological rules are expressed in terms of facets of the flow regime (magnitude, duration, timing, rate of change and quality) and are specified based on best current understanding of the biology of the species being considered. Note that frequency is not included in this set of facets, as frequency typically influences population rather than individual organism responses. In such a case that frequency is known to influence individual responses it should also be included in rule sets to define triggers.

Once individual response triggers are defined, the rules that represent them are applied to a time-series of flow data. The output of this process is a time series of opportunities for the response of interest for each flow time-series (see Figure 1- Definition of opportunities (likelihood)). Because each record (e.g. day) in the time series will either pass or fail the rules as they are defined, the time-series of opportunities will be binary (i.e. 1- opportunity provided or 0- opportunity not provided). For WRP assessment, time-series will represent chosen places

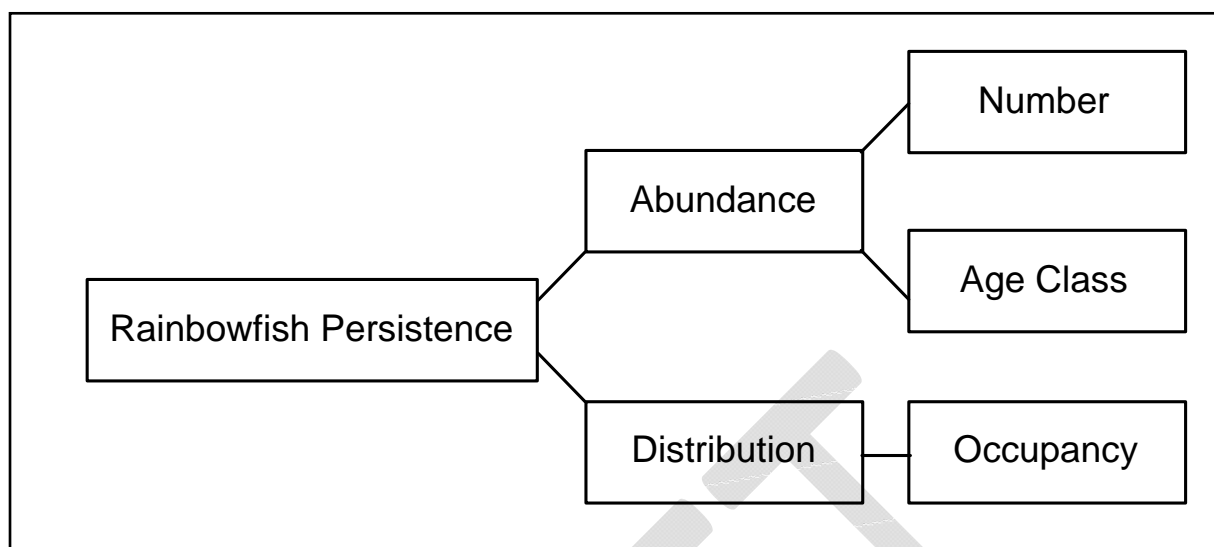

(nodes) in a river network and particular flow management scenarios. They may be a series of gauged or modelled flow. For each node, modelled daily flow sequences representing the pre-development situation (the pre-development case approximating the natural flow regime), current management practices (herein referred to as the current development scenario) and future management practices (herein referred to as the full development scenario) are the minimum set required for this project and a record of approximately 100 years or more is desirable. Alternative management scenarios such as climate change scenarios may also be included.

### **3.3 Ecological Values**

The ecological values associated with the asset that society wishes to maintain are clearly identified. Two examples of such values are Barramundi population persistence and Barramundi for fishing. Values may be broken-down into criteria and sub-criteria that reflect the independent elements that make up the value (Figure 3). It is important that the criteria and sub-criteria are representative of the value and do not repeat or over emphasise any aspects.

It is also important to be both spatially and temporally explicit when defining values. Where in the plan area and when should they be provided? For example, if society values persistence throughout the historical species range of an asset, then the status of the species and its component criteria (number of individuals, age class, patch occupancy) must be maintained at all times and at all nodes.

The relevance of the criteria may vary at different spatial scales – such as when considering values at a node as opposed to over the entire WRP area. For example, patch occupancy is important to consider across the whole plan area, but can be discounted at individual nodes because it is represented by the number of individuals at the node (i.e. one or more individuals present equates to occupancy).

**Figure 3: For an ecological value (e.g. Rainbowfish persistence) a breakdown of the criteria (abundance and distribution) and sub-criteria (number, age class, occupancy) that contribute to its value indicates aspects that need to be considered when assessing how flow management provides for that value.**

### 3.4 Thresholds of Concern (ToC)

The next step is to identify aspects of the availability of opportunities that define the flow-related requirements to maintain the asset value (see Figure 1- Establishing consequence ToC). For instance, important aspects when considering the value 'rainbowfish persistence' may be (1) the frequency of opportunities within spawning seasons and (2) the duration of spells without opportunity in relation to reproductive longevity. These relate to aspects of the frequency and sequence of opportunities over the duration of the time-series. The reproductive longevity of the species is also a key consideration here, as spells without opportunities which exceed this period represent an obvious failure point for species-related values. Critical thresholds which represent acceptable upper and lower levels of change in these opportunities to prevent potential population failure are termed "Thresholds of Concern" (ToC) (after Rogers and Biggs 1999). They are asset-specific hypotheses of the limits of acceptable change following exposure to a known stressor. As such they represent scientifically described endpoints which have been derived using the full extent of the current knowledge base, and are integrated with research and monitoring processes to ensure that there is a continuous testing of their validity. By applying these thresholds to time series of opportunities, likelihood and consequence are in effect integrated to model relative risk.

In order to estimate risk at a node posed by flow management scenarios, the frequency of opportunities estimated from the pre-development (PWRD) scenario is subtracted from the frequency of opportunities from the current and full development scenarios. Frequency analyses of threshold exceedence can then calculate risk statistics for each development scenario at each node. These statistics represent the risk over time of loss of values at nodes from flow scenarios.

### 3.5 Spatial Integration of Risk

The risk to the maintenance of values across the entire plan area (rather than at each node as above) needs to be considered for values that are relevant (and thus defined) at scales broader than individual nodes. This is considered by integrating potential failure at the nodes (e.g. local population abundance falling below a critical threshold abundance) across all relevant nodes in order to identify potential simultaneous failure across space. This analysis utilises the temporal sequence of risk generated by a particular IQQM scenario across all nodes to identify the spatial and temporal patterns of potential failure (Figure 4). Aspects of value resilience (capacity to recover from local failure) need to be considered when evaluating the plan-scale implications of local failures. The impacts of artificial barriers to movement will be important for many values as they may restrict recolonisation. Note that such barriers are absent for the PWRD case.

**Figure 4: A hypothetical example of analysis of temporal sequences of potential loss of a value across multiple nodes to identify simultaneous potential loss within a WRP area. This example is for a single IQQM scenario. The black bars indicate periods of potential failure for each node, with the horizontal axis representing time. The actual time scale will vary to match the definition of asset failure but the analysis will be conducted over the entire IQQM simulation period.**

### 3.6 Risk interpretation

Interpretive narratives for each asset contrast the various IQQM scenarios with the PWRD case in terms of the risk they pose to the maintenance of asset values. They highlight the risk factors in terms of the spatial distribution of risk across nodes and in terms of flow facets (magnitude, frequency, duration, timing, rate of change). Interpretation of the effects of

development scenarios on asset values should be robust so that a lack of better scientific knowledge does not result in inappropriate management decisions and lead to unintended loss of values.

Interpretive narratives also highlight how flow could be changed to decrease the risk to values where it is assessed to have been elevated from the PWRD case and encompass both node-specific and broader catchment issues. This will inform the development of alternative flow management scenarios.

### **3.7 Acceptable change in ecological values and setting plan targets**

The risk assessments for asset values can be used by water planners to inform the process of setting environmental security targets for asset values. These could be expressed in terms of minimum levels of acceptable risk for value measures at each node and across the WRP area. The definition of acceptable risk is not a scientific decision but a social/political one and such targets should be developed in consultation with plan stakeholders. All ecological and economic/social values that are influenced by the WRP should be considered simultaneously and formally when setting targets so that acceptable balances can be found in a transparent and accountable way and so that trade-offs can be fully understood by stakeholders.

### **3.8 Assumptions**

Core assumptions that underpin this approach include:

1. The flow regime as expressed at the WRP reporting nodes represents the flow regime in the WRP area;
2. IQQM development scenarios represent the flow regime that will actually be generated by management under the ROPs (including timing of extraction/supplementation)
3. Effects of barriers to longitudinal connectivity are not explicitly considered in the development cases. Risk to assets may be underestimated if recolonisation processes are impacted by barriers to dispersal.
4. The suite of assets being assessed across the various ecosystem components are representative indicators of the altered flow regime.

### **3.9 Assessment summary**

#### **Ecological Assets and links to flow**

Table 2 provides a summary of the full list of ecological assets and their links to three flow categories. The table indicates the assets that were selected for the ecological risk assessment described in this report. These assets were deemed suitable as there is sufficient knowledge on their life history traits and critical links to flow. Translocated assets were excluded from the risk assessment. A total of 26 assets were used in the risk assessment.

Both riffles and waterholes have been linked to the cease to flow category (Table 2). These assets and a number of freshwater fish, the low flow spawners, have also been linked with the low flows. The medium to high flows are represented by the high flow freshwater fish spawners, wetlands, regional ecosystems and assets within the estuarine and marine fisheries group.

### **Flow Scenarios**

Table 3 details the location and simulation periods of the modelled scenarios used in the risk assessment. It also lists the relevant assets that were analysed at each node or site. The major points to note are:

- The full simulation period (i.e. from 1900) was not used for Nodes 8 and 9 due to low confidence in the modelled flows that occurred before the commencement of gauged records.
- Data from Node 3 Don River at Rannes was unavailable

**Table 2: List of the ecological assets and their links to three flow categories; cease to flow, low flow and medium to high flows. The table also indicates the assets that were included in the detailed ecological risk assessment.**

## 4. Ecological Asset Assessment

### 4.1 Low Flow Spawning Fish Species

#### Methods

Quantitative information about the spawning requirements of *Ambassis agassizii*, *Mogurnda adspersa* and *Melanotaenia splendida splendida* are available from studies conducted in the wild (Milton & Arthington, 1984; Humphrey *et al.*, 2003; Pusey *et al.*, 2004) and in aquaria (Leggett & Merrick, 1987). There are however, no documented studies conducted on these species in the Fitzroy Basin. The information available suggests that all three species have an extended spawning season from spring through to autumn, with a concentrated spawning effort between spring and early summer. It is generally accepted that spawning corresponds with increasing water temperatures and stable water levels, however this may vary between river basins (Pusey *et al.*, 2004).

Spawning occurs in aquatic macrophytes and submerged marginal vegetation and on the substrate (Pusey *et al.*, 2004). In the Fitzroy Basin, most spawning sites are restricted to the marginal habitat (otherwise known as edge habitat) which comprises of root masses from trees and trailing vegetation, leaf litter and woody debris. All three species are batch spawners and have the ability to spawn repeatedly over an extended period, with females depositing upwards of 120 eggs per day for several consecutive days (Pusey *et al.*, 2004). Eggs are attached to the marginal habitat structure where they remain until hatching. The larval period extends from 20-60 days (Pusey *et al.*, 2004). The approach undertaken to identify potential changes to flooding frequencies of low flow spawning fish is summarised below in Figure 5.

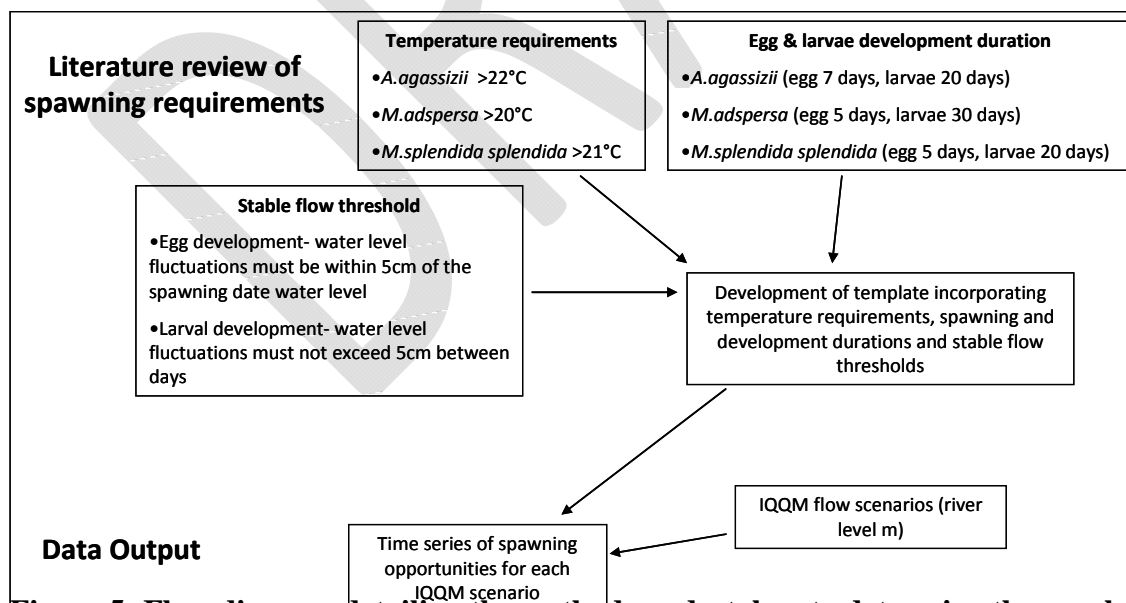

Figure 5: Flow diagram detailing the methods undertaken to determine the number of spawning opportunities per season for low flow spawning fish species

In calculating of the number of spawning opportunities the following spawning requirements were considered:

- Spawning stimulus of a rise in water temperature: 22°C for *A.agassizii*, 20°C for *M.adspersa* and 21°C for *M.splendida splendida*
- Duration of egg and larval development: Egg development of 7 days for *A.agassizii*, 5 days for *M.adspersa* and 5 days for *M.splendida splendida*. Larval development of 20 days for *A.agassizii*, 30 days for *M.adspersa* and 20 days for *M.splendida splendida*
- Stable flow conditions throughout the egg and larval development period

The spawning period for each of the species was derived from water temperature data collected from DERM gauging stations (Appendix A). At each site, an annual water temperature graph, with a daily time step, was plotted using the mean daily water temperatures for each corresponding day over the given period of record. This revealed that all species are likely to spawn during the same months, with spawning beginning in October for all sites and ending in April for sites in the upper catchments (upper Dawson, upper Mackenzie, Nogoia and Comet), May in the middle reaches of the basin (mid-lower Dawson and mid-lower Mackenzie) and June in the Lower parts of the basin (Fitzroy) (Appendix B).

Whilst stable flow conditions are often cited as a requirement of low flow spawning fish, an actual threshold of water level stability for such fish has not been documented. Consequently an average water level rate of change threshold of <0.05m/day (range of 0.01 to 0.1 m/day) was developed for this assessment. This threshold was calculated from the average rate of water level fluctuations observed during stable flow periods of the pre-development scenario, and the potential effects of water level fluctuations on the availability of species' egg laying and spawning habitat (i.e. marginal habitat) for all sites. This rate of change was deemed to have minimal effect on the egg laying and spawning habitat of the low flow spawning fish species. It was assumed that any rate of change greater than 0.05 m/day would cause a negative impact on the availability of spawning habitat.

The application of the water level fluctuation threshold was altered for the egg and larval development phases. The strategy of attaching eggs to a fixed structure results in eggs not being able to move with fluctuations in water level. Consequently, any change in water level from the date they were laid may affect egg viability. To address this, the water level fluctuation threshold was applied from day one of laying eggs and, to ensure egg viability, any change in water level would be required to be within  $\pm 0.05$  m of the day one water level over the egg duration period.

Whilst larvae are active and able to freely move with changes to water level, they still require the marginal habitat as a refuge against predators and adverse environmental variables. Fluctuations in water level can occur, but not in a manner which would limit available refuge or their ability to move to refuge. Therefore, the rate of change between two consecutive days must not exceed the threshold of 0.05 m/day during the larval development period. Thus a gradual rate of increase or decrease is acceptable, but only when the rate of change between days does not exceed 0.05 m/day.

Templates were created using Microsoft Excel© which integrated daily IQQM flow scenarios (back calculated to level in metres) and recruitment opportunity sub-routines, which included the spawning season, egg and larval development durations and acceptable rates of change thresholds. The recruitment opportunity sub-routine was developed such that all three requirements (i.e. spawning season, egg and larval development duration) must be met before recruitment was considered a success.

The recruitment opportunity template was applied to the three IQQM scenarios (pre-development, current development, full development) to generate three daily time series of recruitment opportunities for each node. This was summarised across the entire simulation period to highlight broad differences between the pre-development and each development scenario. The likelihood of water resource development affecting the persistence of populations at each node was calculated as the number of annual recruitment opportunities in the simulation period for each scenario.

A threshold of concern (ToC) was defined to assess the consequence of altering recruitment opportunities for the local (node) population persistence. A theoretical relationship between the annual provision of recruitment opportunity and population maintenance was calculated based on population attributes derived from the literature where possible. Where these parameters were not available it was estimated using a four-step interval elicitation procedure (Speirs-Bridge *et al.* 2008). The ToC was based on the number of annual recruitment opportunities required to maintain equilibrium in the local population size. If the number of annual recruitment opportunities is lower than this threshold, the population abundance is assumed to decline, thus representing a potential threat to the persistence of the local population (Appendix C). Based on the three year reproductive longevity of the species (Pusey *et al.* 2004), it was assumed that three consecutive years with fewer opportunities than the ToC represents a significant threat to the persistence of a local population (i.e. potential local population failure).

The occurrence of three or more consecutive years with fewer opportunities than the ToC was examined for each IQQM scenario. This identified the frequency of potential local population failures for the three cases (pre-development scenario and the two development scenarios).

Risk to the species' persistence across the plan area was assessed by identifying simultaneous occurrences of potential local population failure across multiple nodes. This risk was categorised based on the percentage of nodes experiencing simultaneous potential local population failures (high:  $\geq 75\%$ , moderate: 50 – 74%, low:  $<50\%$ ). Risk was summarised for each IQQM scenario as the percentage of years in each category. Risk from water resource development was interpreted as a change in the risk profiles (i.e. relative proportion of each risk category) between the pre-development scenario and the two development scenarios.

## Results

### *Ambassis agassizii*

Individual nodes experienced increases and decreases in the total number of recruitment opportunities across the simulation period with percentage deviation from the pre-development case ranging between 205% and -51% (Table 4). Annual provision of spawning opportunities showed little variation between scenarios overall (Figure 6), or for many individual nodes (Appendix D). Exceptions included the Dawson River at Woodleigh and at Beckers and the Nogoia River downstream of Fairbairn Dam where the current and full development cases provide greater recruitment opportunities than the predevelopment case. Also, in the Dawson River at Glebe and at Taroom where the full development case provides reduced recruitment opportunities compared to the predevelopment case.

The frequencies of potential local population failures in the current and full development scenarios with respect to the pre-development case were generally either reduced (green shading) or remained unchanged (no shading) (Table 5 and Table 6). The exceptions to this where the comparative prediction was for increased potential local population failures under the development scenarios included Mackenzie River at Carnangarra, Fitzroy River at Wattlebank and Theresa Creek at Gregory Highway.

Across the entire Fitzroy WRP area the risk to *A.agassizii* persistence from water resource management was predicted to be low for both management scenarios as there were no changes to their risk profiles from the predevelopment case (Figure 7). There were never more than 50% of nodes predicted to have simultaneous potential local population failures for any of the three scenarios.

**These results suggest that the value of a persistent population of *A.agassizii* in the Fitzroy WRP area is not threatened by either of the two development scenarios evaluated.**

**Table 4: Total percent deviation of *Ambassis agassizii* recruitment opportunities between IQQM scenarios (green shading: 0% to ± 5%; yellow shading: ±5% to ±15%; orange shading: ±15% to ±25%; red shading: >±25%)**

Figure 7 : Potential risk profile of *Ambassis agassizii* persistence across all sites (nodes)

*Mogurnda adpersa*

Individual nodes experienced increases and decreases in the total number of recruitment opportunities across the simulation period with percentage deviation from the pre-development case ranging between 103% and -68% (Table 7). Annual provision of spawning opportunities showed little variation between scenarios overall (Figure 8), or for many individual nodes (Appendix E). Exceptions included the Dawson River at Woodleigh, Dawson River at Beckers and Nogoia River downstream Fairbairn Dam where the current and full development cases provide greater recruitment opportunities than the predevelopment case. Also, the Dawson River at Glebe, Dawson River at Taroom and Mackenzie River at Carnangarra where the current development case provides reduced recruitment opportunities. The full development case did not reduce or improve spawning opportunities, with the exception of Fitzroy River at Wattlebank, Mackenzie River at Carnangarra, Dawson River at Beckers and Dawson River at Taroom, where there was a reduction in the number of spawning opportunities.

**Table 7: Total percent deviation of *Mogurnda adspersa* recruitment opportunities between IQQM scenarios (green shading: 0% to ± 5%; yellow shading: ±5% to ±15%; orange shading: ±15% to ±25%; red shading: >±25%)**

River	Node	<i>Mogurnda adspersa</i> total number of recruitment opportunities		
		Pre-development	Current development	Full Development
Fitzroy	<b>Wattlebank (Node 1)</b>	900	892	495
	% change from pre-development		-1%	-45%
	% change from current development			-45%
Mackenzie	<b>Bingegang (Node 10)</b>	3607	3915	3503
	% change from pre-development		9%	-3%
	% change from current development			-11%

% change from pre-development		10%	-6%	
% change from current development			-15%	

**Figure 8: Cumulative frequency plot of *Mogurnda adspersa* annual recruitment opportunities across all sites (nodes). Dashed line indicates the threshold of concern (10 or more opportunities per annum), necessary to maintain population equilibrium.**

The frequencies of potential local population failure in the current and full development scenarios with respect to the pre-development case were generally either reduced (green shading) or remained unchanged (no shading) (Table 8 and Table 9). Exceptions to this, where the comparative prediction was for increased potential local population failures under the development scenarios, included Mackenzie River at Carnangarra, Fitzroy River at Wattlebank and Theresa Creek at Gregory Highway.

Across the entire Fitzroy WRP area the risk to *M.adspersa* persistence from water resource management was predicted to be low for both development scenarios as there were no changes to their risk profiles from the predevelopment case (Figure 9). There were never more than 50% of nodes predicted to have simultaneous potential local population failures for any of the three scenarios.

**These results suggest that the value of a persistent population of *M.adspersa* in the Fitzroy WRP area is not threatened by either of the two development scenarios evaluated.**

**Table 8: Differences in *Mogurnda adspersa* predicted potential local (node) population failures for the current development scenario in comparison with the predevelopment scenario (0 = no change; -1= current development with reduced prediction of population failure (green); 1 = current development with increased prediction of population failure (red)).**

Figure 9 : Potential risk profile of *Mogurnda adspersa* persistence across all sites (nodes).

*Melanotaenia splendida splendida*

Individual nodes experienced increases and decreases in the total number of recruitment opportunities across the simulation period with percentage deviation from the pre-development case ranging between 81% and -51% (Table 10). Annual provision of spawning opportunities showed little variation between scenarios overall (Figure 10), or for many individual nodes (Appendix F). Exceptions included the Dawson River at Woodleigh, Dawson River at Beckers and Nogoia River downstream Fairbairn Dam where the current and full development cases provide greater recruitment opportunities than the predevelopment case. Also, the Dawson River at Glebe where the current and full development cases provide reduced recruitment opportunities.

**Table 10: Total percent deviation of *Melanotaenia splendida splendida* recruitment opportunities between IQQM scenarios (green shading: 0% to ± 5%; yellow shading: ±5% to ±15%; orange shading: ±15% to ±25%; red shading: >±25%)**

River	Node	<i>Melanotaenia splendida splendida</i> total number of recruitment opportunities		
		Pre-development	Current development	Full Development
Fitzroy	<b>Wattlebank (Node 1)</b>	2099	1608	1633
	% change from pre-development		-23%	-22%

% change from current development			0%	
<b>Utopia Downs (Node 7)</b>	3410	3238	3238	
% change from pre-development		-5%	-5%	
% change from current development			0%	

**Figure 10: Cumulative frequency plot of *Melanotaenia splendida splendida* annual recruitment opportunities across all sites (nodes). Dashed line indicates the threshold of concern (17 or more opportunities per annum), necessary to maintain population equilibrium.**

The frequencies of potential local population failure in the current and full development scenarios with respect to the pre-development case were generally either reduced (green shading) or remained unchanged (no shading) (Table 11 and Table 12). Exceptions to this, where the comparative prediction was for increased potential local population failures under the development scenarios, included Mackenzie River at Carnangarra, Fitzroy River at Wattlebank and Theresa Creek at Gregory Highway.

Across the entire Fitzroy WRP area the risk to *M.splendida splendida* persistence from water resource management was modelled to be low for both development scenarios as there were no changes to their risk profiles from the predevelopment case (Figure 11). There were never more than 50% of nodes predicted to have simultaneous potential local population failures for any of the three scenarios.

**These results suggest that the value of a persistent population of *M.splendida splendida* in the Fitzroy WRP area is not threatened by either of the two development scenarios evaluated.**

**Table 11: Differences in *Melanotaenia splendida splendida* predicted potential local (node) population failures for the current development scenario in comparison with the predevelopment scenario (0 = no change; -1= current development with reduced prediction of population failure (green); 1 = current development with increased prediction of population failure (red)).**

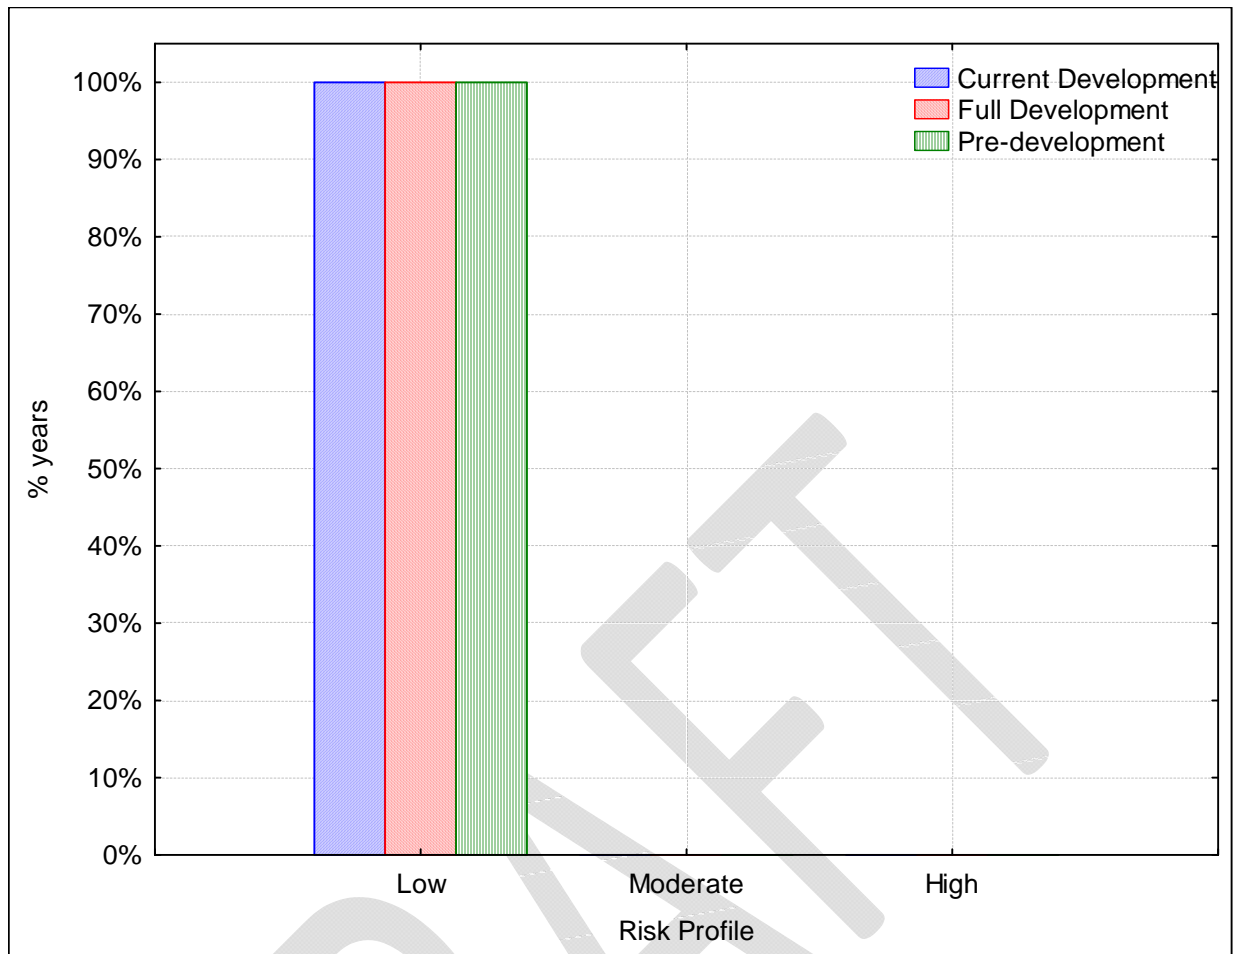

Figure 11 : Potential risk profile of *Melanotaenia splendida splendida* persistence across all sites (nodes).

## 4.2 Floodplain Riparian Vegetation Communities (with specific emphasis on *Eucalyptus coolabah*)

### Methods

Floodplain riparian ecosystems in sub-coastal Queensland have received little attention in the literature; in particular there is a lack of quantitative information regarding their ecological and flooding requirements. However, there is a general consensus that the magnitude, frequency and duration of flood events greatly affect the distribution, maintenance and regeneration ability of riparian vegetation zones.

The method used to identify potential changes to flooding magnitude, frequency and duration on flooded riparian vegetation communities is summarised below (Figure 12) and uses *Eucalyptus coolabah* (Coolabah) as an indicator species. The method uses spatial information (contour data) and vegetation community distributional data (Regional Ecosystem data) to develop percent inundation surface models for vegetation communities at sites associated with IQQM nodes. A percent inundation rating curve is created whereby modelled flow data can be applied and a daily time series of percent inundation created for each IQQM scenario.

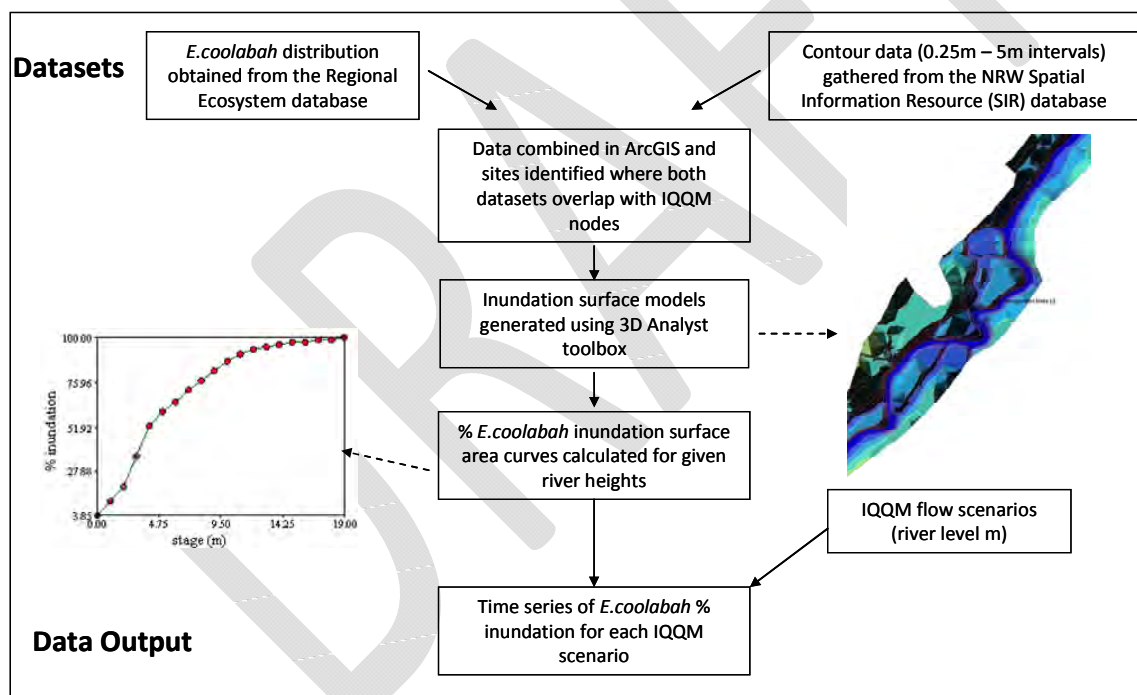

Figure 12: Process used to develop a GIS percentage *E. coolabah* inundation model.

Riparian vegetation community distribution was based on current Regional Ecosystem (RE) data (EPA, 2007). Regional ecosystems are defined as 'vegetation communities in a bioregion that are consistently associated with a particular combination of geology, landform and soil (Sattler & Williams, 1999). Information about regional ecosystems is derived from a broad range of existing information sources including land system, vegetation and geology mapping and reports (Sattler & Williams, 1999).

Eucalyptus coolabah is widely distributed in temporarily inundated areas and is a dominant species of the riparian community which covers over 5,100 km<sup>2</sup> of the Fitzroy Basin (Figure 13). Regional Ecosystem data was accessed through the DERM Spatial Information Resource (SIR) (DERM, 2008). An assessment of these data revealed nine REs containing Coolabah (Table 13), of which three (11.3.3, 11.3.4, 11.3.25) contribute approximately 82% of the total distribution. Many of these communities are listed under both the Vegetation Management Act (1999) and EPA Biodiversity status as either "Endangered" or "Of Concern", principally as they have been either extensively modified by grazing and have had vast tracks cleared for cropping and grazing (Sattler & Williams, 1999).

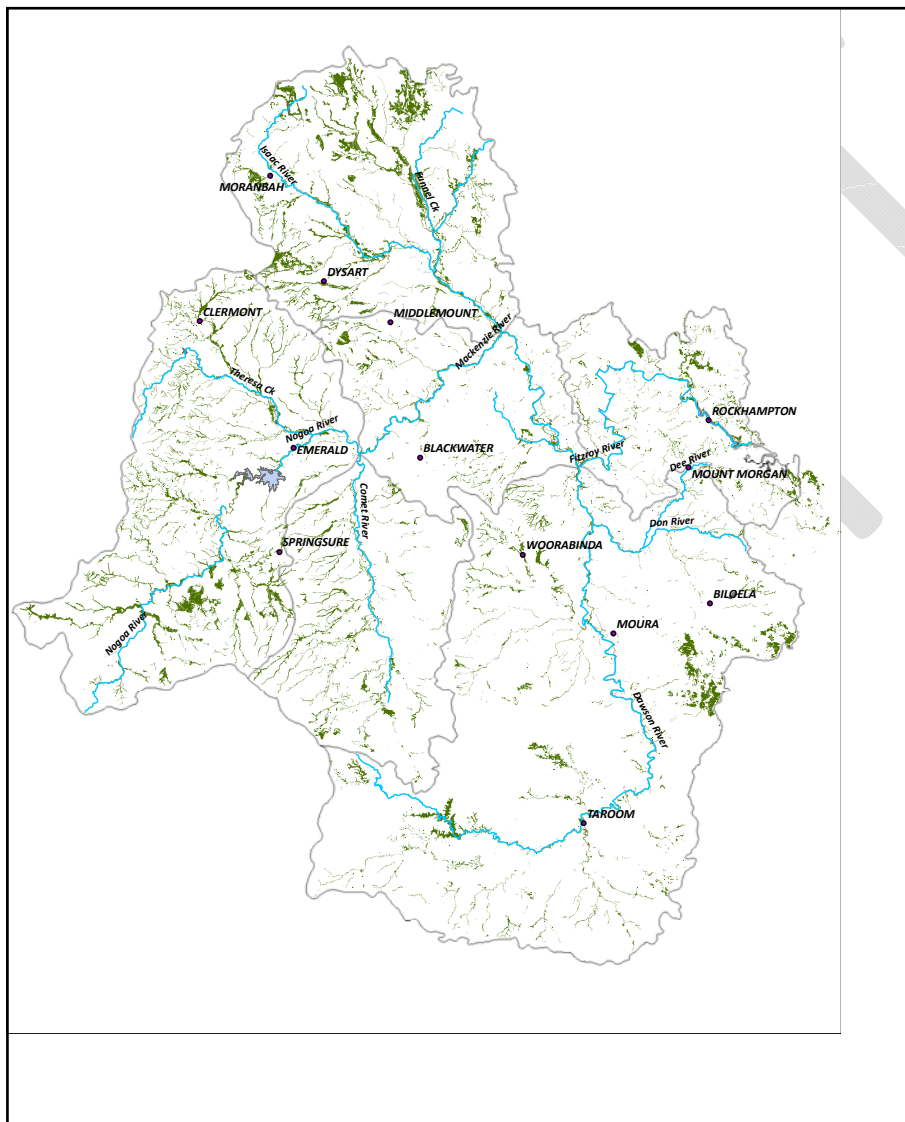

Figure 13: Distribution of *E. coolabah* dominated Regional Ecosystem communities of the Fitzroy Basin (EPA, 2007)

**Table 13: Regional Ecosystem types used in the assessment of *E. coolabah* communities of the Fitzroy Basins**

Regional Ecosystem	Description	Area within Fitzroy Basin (km <sup>2</sup> )	Vegetation Management Act 1999 (VMA) status	EPA Biodiversity Status
11 3 1	<i>Acacia harpophylla</i> and/or <i>Casuarina cristata</i> open forest on alluvial plains	483 84	Endangered	Endangered
11 3 3	<i>Eucalyptus coolabah</i> woodland on alluvial plains	1071 99	Of Concern	Of Concern
11 3 4	<i>Eucalyptus tereticornis</i> and/or <i>Eucalyptus</i> spp tall woodland on alluvial plains	1282 06	Of Concern	Of Concern
11 3 15	<i>Eucalyptus coolabah</i> , <i>Acacia stenophylla</i> , <i>Muehlenbeckia cunninghamii</i> fringing woodland on alluvial plains	0 02	Of Concern	Of Concern
11 3 21	<i>Dichanthium sericeum</i> and/or <i>Astrebla</i> spp grassland on alluvial plains Cracking clay soils	282 65	Endangered	Endangered
11 3 25	<i>Eucalyptus tereticornis</i> or <i>E. camaldulensis</i> woodland fringing drainage lines	1846 61	Not Of Concern	Of Concern
11 3 27	Freshwater wetlands	57 80	Not Of Concern	Of Concern
11 3 37	<i>Eucalyptus coolabah</i> fringing woodland on alluvial plains	105 82	Not Of Concern	No Concern

Source: EPA, 2007

Contour data were accessed through the DERM Spatial Information Resource (SIR) database (DERM, 2008). These contour data were generated using Digital Elevation Models (DEM) interpolated from photogrammetric digital data purchased from the Australian Surveying and Land Information Group (AUSLIG). Contour data at less than 5 metre intervals were used in the assessment as contours greater than 5 metre were considered too coarse and unable to provide the required detail.

The assessment of Coolabah populations was undertaken for ten sites throughout the Basin, including three in the Nogo/Mackenzie and Dawson Rivers and two in the Comet and Fitzroy Rivers (Table 14). In generating the percent inundation surface models the following requirements were specified:

- Coolabah distribution must be greater than 500 hectares
- Contour datasets must be with intervals less than 5 metres
- There must be an overlap between the distribution and contour datasets
- Sites must be within close proximity upstream of IQQM nodes- the method for back calculating flow (ML/day) to river height (m) is site specific and therefore only applies to that site
- A change in riverbed height must be less than 1m over the entire study site
- The lowest river bed height must be known in Australian Height Datum (AHD) - in all instances this was the cease to flow level for the gauging stations associated with each node

**Table 14: Details of *E. coolabah* sites assessed**

Catchment	General Location	RE Location	Coolibah stand size (ha)	Contour intervals	Riverbed Elevation (AHD)	Minimum Coolibah elevation (AHD)	Maximum Coolibah elevation (AHD)
Nogoa/Mackenzie	Lower Nogoa	Bridge Flat road	1059	0.25m	156	158	167
	Mid Mackenzie	Bingegang	1426	2m	100	100	120
	Lower Mackenzie	Duaringa Apis Rd	2614	1m	47	47	85
Dawson	Mid Dawson	Woodleigh	2923	2m	110	110	128
	Mid Dawson	Isla Delusion	1830	2m	144.3	144	159
	Lower Dawson	Beckers	824	2m	64.5	65	84
Fitzroy	Upper Fitzroy	Riversleigh	827	1m	33.5	34	71
	Lower Fitzroy	Yamba	1130	5m	5	5	25
Comet	Upper Comet	The Lake	550	2m	186	186	202
	Lower Comet	Comet Weir	2792	2m	142	140	168

The percent inundation surface models were generated in ArcGIS 3D Analyst Geoprocessing toolbox (ESRI ArcMAP 9.3). For each site, a Triangulated Irregular Network (TIN) was constructed using regional ecosystem polygon data and contour lines. Each TIN was assessed at 1 m intervals using the Surface Volume function, which calculated the surface area inundated relative to a given river height.

The inundation values were converted to a percentage of the maximum inundation value and imported into the Rating Curve function of the River Analysis Package (Version 2.0.4) (eWater, 2008). These values were applied to each of the three IQQM scenarios (scenarios back-calculated to height in m) to generate three daily time series of percent inundation for each node. This was summarised across the entire simulation period to highlight broad differences between the pre-development and each of the two development scenarios.

A threshold of concern (ToC) could not be derived as the inundation requirements of Coolabah and other riparian communities are largely unknown. Therefore only the likelihood of water resource development potentially changing the magnitude, frequency and duration of flood events was assessed for each site and across the plan area.

The magnitude of events was assessed as the proportional change between scenarios of the percent yearly maximum inundation. This was conducted on a yearly basis with a year being July 1st to June 30th the following year. The flood event duration was assessed as the proportional change between scenarios for the total number of days above the 25%, 50% and 75% riparian community inundation levels. These levels generally correspond to the instream channel riparian zone (<50% inundation), upper riparian zone (<75% inundation) and floodplain riparian zone (>75% inundation). The proportional change between scenarios for the average length of days between flood events at the 25%, 50% and 75% riparian community inundation levels was also assessed to identify any potential changes in the frequency of these flood events.

## Results

Maximum percent inundation was reduced at all sites, with deviation from pre-development ranging from -2% to -41% and 0% to -39% deviation from current development to full development (Table 15). Sites experiencing the greatest deviation from pre-development include Nogoia River at Bridge Flat Road, Mackenzie River at Bingegang, Dawson River at Woodleigh and Dawson River at Isla Delusion. Overall, greatest deviation between scenarios was experienced between 5% and 80% maximum yearly inundation (Figure 14).

All sites experienced a reduction in flow duration above 25%, 50% and 75% Coolabah inundation level (Table 16). Overall deviation from predevelopment varied little between the three inundation levels, with deviations ranging from -13% to -24% and -6% to -11% deviation from current development to full development. Sites experiencing the most deviation from pre-development included Nogoia River at Bridge Flat Road, Mackenzie River at Bingegang, Dawson River at Beckers, Dawson River at Woodleigh and Dawson River at Isla Delusion.

The annual flow duration varied between IQQM scenarios, with fewer number of inundation days in the full and current development scenarios (Figure 15). This is most evident above the 10% time exceedence threshold.

The number of days between 25%, 50% and 75% inundation levels increased under the current and full development scenarios (Table 17; Figure 16). Overall deviation from predevelopment ranged from 7% to 108% for the 25% inundation level, 0% to 85% for the 50% inundation level and 0% to 52% for the 75% inundation level. Sites experiencing the greatest deviation increase included Nogoia River at Bridge Flat Road, Mackenzie River at Bingegang, Dawson River at Beckers, Dawson River at Woodleigh and Dawson River at Isla Delusion. There was a general decrease in deviation at the higher inundation levels.

**These results indicate that the value of Coolabah persistence in the Fitzroy WRP area is potentially at higher risk under the two development scenario evaluated.**

**Table 15: Total percent deviation of *Eucalyptus coolabah* yearly maximum percent inundation between IQQM scenarios (green shading 0% to -5%; yellow shading -5% to -15%; orange shading -15% to -25%; red shading >-25%)**

River	Site	Average <i>E.coolabah</i> inundation (% max/year)		
		Pre-development	Current Development	Full Development
Overall	All sites	51%	46%	43%
	% change from pre-development		-10%	-16%
	% change from current development			-6%
Fitzroy	Yamba	58%	56%	54%

### 4.3 *Lates calcarifer* (Barramundi)

#### Methods

*Lates calcarifer* (Barramundi) are widely distributed throughout northern Australia, occurring in rivers from Shark Bay (Western Australia) to the Mary River (Queensland). Barramundi are a long lived species; their longevity is commonly 9-10 years (Pusey *et al.* 2004), with records of fish living up to 32 years in the Fitzroy estuary (Halliday *et al.* 2007). Barramundi are catadromous, typically migrating from freshwater to saltwater to spawn. Although access to freshwater habitats is not obligatory (Pender and Griffin, 1996), it can be advantageous in promoting juvenile growth (Milton *et al.* 2007). Barramundi are protandrous hermaphrodites, beginning life as a male and changing into females soon after spawning (Pusey *et al.* 2004). In Australia, barramundi spawn during spring and summer, although the timing of spawning activity is known to vary between catchments and years (Robins *et al.* 2007).

The persistence of barramundi in the Fitzroy basin and surrounding creek systems is influenced by a variety of activities. The development of water infrastructure, most notably the Fitzroy Barrage, has significantly impacted natural populations of freshwater barramundi. Cotterell & Jackson (1999) highlighted that there is ample evidence (both qualitative and quantitative) to

suggest that the Fitzroy Barrage (completed in 1970) has significantly prevented migration of the species to its former range. Barramundi were once collected as far upstream as the Connors River, Mackenzie/Comet/Nogoa River junction and Dawson River at Theodore, and are now extensively stocked in order to satisfy recreational demand.

Habitat quantity and quality along the coastal and floodplain regions have also been affected. Extensive development of some 16,000 ha of ponded pasture systems in or adjacent to coastal wetlands (such as supralittoral habitats) of central Queensland has dramatically changed the structure of these habitats and impeded fish migration (Hyland, 2002). Floodplain lagoons and wetlands have also been substantially impacted through loss of river connectivity through levees and bund walls, degradation of habitat structure and water quality through grazing and invasion of weed species, such as Para Grass (*Brachiaria mutica*) and Water Hyacinth (*Eichhornia crassipes*).

The Fitzroy estuary and surrounding creek systems, is one of a few worldwide which have had detailed research conducted on the effects of freshwater flows on barramundi populations. This is despite numerous aspects of barramundi life history suggesting that populations are likely to be highly responsive to freshwater flows (Robins *et al.* 2007).

One such project, led by the Queensland Department of Primary Industries and Fisheries (DPIF), was entitled 'Environmental flows for sub-tropical estuaries: understanding the freshwater needs of estuaries for sustainable fisheries production and assessing the impacts of water regulation' (Halliday and Robins, 2007). This multifaceted project investigated a range of important fisheries species with the main objectives to:

- Review the current knowledge of the relationship between freshwater flows and estuarine fisheries production.
- Develop a logical framework for investigating:
  - (i) the role of freshwater flow; and
  - (ii) the effects of modified flows, on estuarine fisheries production.
- Correlate historical flow and fisheries production data of sub-tropical estuaries.
- Develop procedures for assessing the changes in Queensland's estuarine fisheries production that result from water abstraction and regulation.
- Develop and communicate guidelines on environmental flows for estuarine fisheries to water managers, water users, the fishing industry and the general community.

Results of this project provided quantitative evidence that there are substantial benefits to barramundi production from allowing freshwater flows to reach the estuary. These benefits include providing lateral connectivity to facilitate the movement of fish from freshwater reaches to estuarine sections, newly recruited fish from marine spawning areas to estuarine and freshwater habitats, and delivering nutrients into the estuary that may be attributed to the increases in growth rates of fisheries species (Halliday & Robins, 2007) (Table 18).

The report titled 'Use of 12 Mile Creek by Barramundi: Effects of Local Climate 1984-2007' (Sawynok and Platten, 2008) also documents aspects of barramundi recruitment within the Fitzroy estuary and surrounding creek, wetland and lagoon systems. The report was the culmination of 23 years of research collected under a number of monitoring and tagging programs and research organisations (e.g. InfoFish, CapReef, Suntag), with the objectives to (Sawynok and Platten, 2008):

1. Describe the use of 12 Mile Creek by Barramundi over the 23 year period.
2. Describe the influence of local climatic conditions, especially rainfall, on the use of the habitat by barramundi.
3. Review long term trends on the use of 12 Mile Creek by Barramundi in relation to changes in the local climate.

The outcomes of this report were that climate change resulted in a reduction of waterhole habitat use, an increase in time between peak recruitments, a decrease in the survival of first year post-winter recruits, a reduction in overall growth rates of barramundi and a reduction in the distribution of Barramundi genetics to other populations, especially those to the south

(Sawynok and Platten, 2008). A clear and strong relationship between barramundi recruitment and the timing and magnitude of freshwater flow events from the Fitzroy River was identified (Sawynok and Platten, 2008).

The outcomes of these studies were utilised to identify the risk to the growth and recruitment of barramundi populations in both the Fitzroy estuary and surrounding creek systems. The results of these projects were discussed during separate meetings with Dr Ian Halliday (DPIF Senior Fisheries Biologist), Bill Sawynok (InfoFish Services) and Dr John Platten (DERM and Capricorn Bunker Consulting). Details were provided concerning the approach that DERM were taking in assessing the risk posed to the ecological assets. Further information pertaining to the reports and general information about barramundi in the Fitzroy estuary were also discussed. A series of models on barramundi recruitment and growth were then provided which could be applied to IQQM modelled datasets (see below).

### **Relationship between Barramundi Year Class Strength (YCS) and freshwater flow**

The methods and data presented below are summarised from Chapter 6 of the DPIF project detailed above. For further details consult Halliday et al (2007a). The year class strength (YCS) of Fitzroy estuary Barramundi were determined using the age-structures of the commercial catch of barramundi collected over five consecutive years in the Fitzroy estuary.

In total 2112 barramundi were aged using sagittal otoliths during the five consecutive 'sampling years' (year-1 = 2000/01, year-2 = 2001/02, year-3 = 2002/03, year-4 = 2003/04 and year-5 = 2004/05). Sampling occurred twice each 'sampling year', once in the week(s) preceding the seasonal fishing closure (October) and then again in the week(s) after the opening of the fishery (February).

The barramundi catch ranged in age from 2 years old to 32 years old; 8.3% of the sampled catch aged as two years old, 88.4% of the catch aged between 3 and 11, 2.0% of the catch aged between 12 and 20 years old and 1.3% of the sampled catch aged as greater than 20 years old. The standardised residuals from the catch-curve regressions were used to give an indication of relative YCS for barramundi aged between 3 to 11 years old. When compared against summer flow, the year-class strength of barramundi fluctuated and was significantly and positively correlated ( $p < 0.001$ ), however the goodness-of-fit was relatively low ( $R^2 = 0.3732$ ) (Figure 17; Figure 18). The resulting linear equation (Figure 18) was applied to log<sub>10</sub> summer (December-February) IQQM modelled data (Pre-development, Current Development, Full Development) to generate three yearly time series of YCS.

A threshold of concern (ToC) was defined to establish the consequence of altering YCS on barramundi populations. A theoretical relationship between YCS and population maintenance was calculated using the thresholds described in Halliday *et al* (2007a) where strong (>0.5 YCS index), moderate (0.5 to -0.5 YCS index) and poor (<-0.5 YCS index) years were identified. The proportional change between scenarios was calculated to identify changes between years of strong, moderate and poor YCS.

Strong recruitment years were considered to be those required to maintain a healthy barramundi population and the greater the number of years between these events, the higher potential risk to barramundi populations. A high risk profile (i.e. potential local population failure) was defined as any year where the number of consecutive years without strong recruitment exceeded the longevity of most barramundi of 11 years. A moderate risk profile was defined as any year where the number of consecutive years without strong recruitment was between the average age of protandry of 5 years (Pusey *et al.* 2004, Sawynok pers com) and the high risk profile. All other years were deemed as being low risk to barramundi populations. Overall risk from water resource development was interpreted as a change in the risk profiles (i.e. relative proportion of each risk category) between the pre-development scenario and the two development scenarios.

Figure 17 : Residuals from catch-curve regressions of barramundi and king threadfin against summer freshwater flows from the Fitzroy River estuary

**Figure 18: Scatter plot of catch-curve regressions of Barramundi against summer freshwater flows from the Fitzroy River estuary.**

### Relationship between Barramundi growth and freshwater flow

The methods and data presented below are summarised from Chapter 7 of the DPIF project details above. For further details consult Robins *et al.* (2007b).

Tag-recapture data were obtained from the Suntag Program of the Australian National Sport Fishing Association Queensland Inc. (ANSA Qld). A total of 1,168 tagged and recaptured barramundi between October 1984 and November 2004 were used in the assessment. Time-at-liberty, length-at-release, length-at-recapture, release year, release month, recapture year, recapture month, release location type, and recapture location type were calculated. Only Fitzroy River catchment records, time-at-liberty (in days) >30 and <366 and change in total length >0 mm were selected for analysis. Barramundi growth was estimated using the seasonal form of the von Bertalanffy equation, with the equation directly incorporating the effects of time-at-liberty, seasonality, and length-at-release. The effects of flow on growth rates were incorporated into the growth coefficient.

The resulting barramundi growth equations were split over a number of size classes and seasons. For the purpose of this assessment the growth equation for barramundi <420 mm were applied, which was of the form:

**Barramundi Growth (mm/day) = a + b\*LN (weekly flow in ML) where:**

	Summer	Autumn	Winter	Spring
a	-0.31159	-0.17263	-0.01014	-0.1511
b	0.107743	0.059681	0.003506	0.052243

The equation was applied after flow reached 1,300 ML per week as growths prior to this threshold were constant (Figure 19).

**Figure 19: Thresholds of the effect of freshwater flow-during-liberty on seasonal growth rates of juvenile barramundi within the Fitzroy River estuary (note x-axis as log10 scale)**

The seasonal equations were applied to respective weekly IQQM modelled data (Pre-development, Current Development, Full Development) to generate three daily time series of weekly barramundi growth.

A threshold of concern (ToC) could not be applied as the link between barramundi growth, survivorship and abundance has not been quantified. Therefore only the likelihood of water resource development potentially affecting barramundi growth was assessed for each season and on a yearly basis using growth frequency duration graphs and as a proportional change between scenarios.

### Relationship between juvenile Barramundi recruitment and freshwater flow

Juvenile barramundi (<250 mm) recruitment in the 12 Mile creek system was identified from 23 years of fish tagging (1984 to 2008; including recaptures), cast netting (1999 to 2008) and electrofishing data (2006 to 2008), and collections following major fish kill events (early winter 2001, November 2005, late 2006).

Recruitment of barramundi into 12 Mile Creek was found to be dependent on the success of spawning in the adjacent Fitzroy River delta, the timing and volume of Fitzroy River flows and localised coastal rainfall events (Figure 20; Figure 18). Strong recruitment was observed when the total volume of wet season flows were > 1500 GL, the timing of the maximum flow events occurred during January and February, at least one monthly wet season flow exceeded 400 GL and when the localised rainfall during January and February exceeded 140 mm (green shading; Figure 18). In years when either the timing or the flow volume were outside the range (red shading; Figure 18) then recruitment was significantly low. In the remaining years when

conditions were close to the range (yellow/green shading; Figure 18) there was a moderate level of recruitment.

**Figure 20: Recruitment of Barramundi in 12 Mile Creek related to log wet season flows (November-March). [Note the reduction in scale of 1996 recruitment which was actually 1,271] (adapted from Sawynok & Platten, 2008)**

**Table 19: Relationship between Barramundi recruitment, river flows in the Fitzroy River, rainfall at 12 Mile Creek and timing of flows (adapted from Sawynok & Platten, 2008).**

YEAR	FLOW AND TIMING				RECRUITS		FITZROY RIVER			12 MILE

The flow parameters of the barramundi recruitment model were applied to the log10 wet season (November to March) IQQM modelled data (Pre-development, Current Development, Full Development) to generate three yearly time series juvenile barramundi recruitment.

A threshold of concern (ToC) was defined to establish the consequence of altering juvenile recruitment on 12 Mile Creek barramundi populations. A relationship between juvenile recruitment and population maintenance was calculated using the number of flow parameters which were met during each year. The proportional change between scenarios was calculated to identify changes between years of strong recruitment (all three flow parameters met), moderate recruitment (1 or 2 flow parameters met) and poor recruitment (no flow parameters met).

The strong juvenile barramundi recruitment was adopted as the threshold of concern (ToC). A high risk profile (i.e. potential local population failure) was defined as any year where the number of consecutive years without strong recruitment exceeded the most common longevity of barramundi, 11 years. A moderate risk profile was defined as any year where the number of consecutive years without strong recruitment was between the average age of protandry of five years (Pusey et al. 2004, Sawynok pers com) and the high risk profile. All other years were

deemed as being low risk to barramundi populations. Overall risk from water resource development was interpreted as a change in the risk profiles (i.e. relative proportion of each risk category) between the pre-development scenario and the two development scenarios.

## **Results**

### **Relationship between Barramundi Year Class Strength (YCS) and freshwater flow**

Assessment of the pre-development scenario revealed up to 67% of years in the IQQM simulation period contained flows which would result in moderate barramundi recruitment (Table 20). Less than 5% of the total years modelled resulted in poor recruitment with the remainder years (28%) containing strong recruitment.

Comparisons between pre-development and development scenarios revealed a decrease in strong recruitment years, minor decrease in moderate recruitment years and an increase in poor recruitment years (Table 20). Likewise, comparisons between current development and full development scenarios revealed a decrease in strong recruitment years and an increase in the number of poor recruitment years. Most differences between IQQM scenarios were observed between 0.4 to -0.7 YCS regression residuals (Figure 21), with the greatest deviation occurring around the -0.1 YCS with a 15% deviation in time exceedence.

Risk to barramundi persistence from water resource management varied between scenarios, with an increased risk to barramundi persistence under the full development scenario (Figure 22). There was little variation in risk between pre-development and current development scenarios, with the vast majority of years (>95%) at either low or moderate risk (Figure 22). The risk to barramundi YCS was greatest in the full development scenario, with 17% of the modelled years at high risk (Figure 22).

**These results indicate that the value of a persistent population of barramundi in the Fitzroy WRP area is at higher risk under the full development scenario evaluated.**

**Table 20: Total percent deviation of *Lates calcarifer* Year Class Strength (YCS) for strong, moderate and poor recruitment years (green shading 0% to ±5%; yellow shading ±5% to ±15%; orange shading ±15% to ±25%; red shading >±25%)**

Fitzroy Estuary Barramundi YCS	% of years		
	Pre-development	Current Development	Full Development
<b>Strong YCS</b>	28%	25%	23%
% change from pre-development		-10%	-17%
% change from current development			-7%
<b>Moderate YCS</b>	67%	66%	66%
% change from pre-development		-1%	-1%
% change from current development			0%
<b>Poor YCS</b>	5%	8%	10%
% change from pre-development		80%	120%
% change from current development			22%

**Figure 21: Cumulative frequency plot of *Lates calcarifer* Year Class Strength (YCS)**

**Figure 22 : Potential risk profile of *Lates calcarifer* persistence based upon assessment of Year Class Strength (YCS).**

**Relationship between Barramundi growth and freshwater flow**

There was a negligible reduction in barramundi growth between pre-development and development scenarios, with differences ranging from 0% to -7% (Table 21; Figure 23). Reduced growth was observed mostly during summer with a -0.7% decrease between pre-development and the full development scenario (Table 21; Figure 23).

**These results indicate that the value of Barramundi growth in the Fitzroy WRP area is unlikely to be threatened by either of the two development scenarios evaluated.**

**Table 21: Total percent deviation of *Lates calcarifer* growth (mm/day) on an annual and seasonal basis (green shading 0% to -5%; yellow shading -5% to -15%)**

Season	Average Weekly Barramundi growth (mm)		
	Pre-development	Current Development	Full Development
<b>All seasons</b>	0.37	0.36	0.35
% change from pre-development		-4%	-5%
% change from current development			-1%
<b>Summer</b>	0.80	0.76	0.75
% change from pre-development		-6%	-7%
% change from current development			-1%
<b>Autumn</b>	0.39	0.39	0.38

% change from current development			0%

Figure 23: Cumulative frequency plot of *Lates calcarifer* growth (mm/day) across all years and seasons

**Relationship between juvenile Barramundi recruitment and freshwater flow**

The percent of years with strong barramundi recruitment into 12 Mile Creek decreased by up to 24% between pre-development and development scenarios (Table 22). This decrease in strong years saw an increase in the number of years with moderate or poor recruitment. There were negligible differences between the two development scenarios, except for an increase of 10 % of poor recruitment years under the full development scenario.

The maximum spell length between strong recruitment years was seven for the predevelopment scenario and 12 for both development scenarios (Figure 24). There was little variation between both development scenarios.

Overall risk to barramundi populations was low for the pre-development case, with over 90% of the modelled years having a low risk profile (Figure 25). The risk profiles for both development cases were the same and showed a higher risk as a result of water resource management. Approximately 3% of years were at high risk (i.e. the number of years between strong recruitment opportunities exceeded barramundi longevity) and 18% at moderate risk (i.e. the number of years between strong recruitment opportunities exceeded the age at protandry, but less than barramundi longevity). Fewer than 80% of years were under low risk.

**These results indicate that the value of a persistent population of Barramundi in 12 Mile Creek is at higher risk under both development scenarios evaluated.**

**Table 22: Total percent deviation of *Lates calcarifer* recruitment into 12 Mile Creek for strong, moderate and poor recruitment years (green shading 0% to ±5%; yellow shading ±5% to ±15%; orange shading ±15% to ±25%)**

12 Mile Ck Juvenile Barramundi recruitment	% of years		
	Pre-development	Current Development	Full Development

#### 4.4 *Penaeus merguensis* (Banana Prawn)

##### Methods

*Penaeus merguensis* (Banana prawn) is a significant target species in the trawl fisheries of northern Australia. Banana prawn is an estuarine and coastal species occurring in waters up to 20 km from the coast and up to 45 m water depth (Robins *et al.* 2007; Grey *et al.* 1983). Banana prawns are a short lived species, completing their entire lifecycle within 12 months. Spawning occurs in marine environments throughout the year, with a peak spawning effort occurring during spring and autumn. Mangrove lined creeks are the preferred habitat of post-larvae and juveniles where recruitment and growth occur. Downstream migration of adolescent banana prawns outside of the estuary is associated with seasonal rainfall and flow events.

Banana prawns are relatively well researched with most studies demonstrating total commercial catch increasing in proportion to summer freshwater flow (Robins *et al.* 2007; Browder 1985; Vance *et al.* 1985; Evans *et al.* 1997; Vance *et al.* 1998; Galindo-Bect *et al.* 2000). Two studies have been undertaken in the Fitzroy estuary investigating this relationship. Robins *et al.* (2007) found a positive correlation between commercial catch and freshwater flow and proposed that increased flows improve catchability and recruitment of banana prawns. Robins *et al.* (2007) further explored this relationship and identified that juvenile prawn growth is significantly related to increased freshwater flows. The outputs of the research undertaken by Robins *et al.* (2007) has been used in the method implemented to identify the potential risk to prawn growth and recruitment in response to changes in flow regime.

Fitzroy estuary banana prawn populations were collected over four 'sample years' (year 1 = 2001/02; year 2 = 2002/03; year 3 = 2003/4; year 4 = 2004/05) and comprised of 51 separate sample trips. Four regions were sampled on a fortnightly basis from October to May. Shallow water areas (i.e. <1 m deep) adjacent to creeks and drainage channels of banks in the main river were sampled on the low tide using a beam trawl net (1 m high, 0.5 m wide, 6 mm mesh). All banana prawns caught were measured to a truncated 1 mm carapace length size class.

Banana prawn growth was estimated using the nonlinear von Bertalanffy equation of the form:

$$\text{Length}_2 = \text{Length}_1 + (L_\infty - \text{Length}_1) * [ 1 - \exp ( -\{ a + kc * \text{temp} + kd * \text{temp}^2 + ke * \text{flow}_0 + kf * \text{flow}_0^2 + kg * \text{flow}_4 \} * \text{Days} + b ) ]$$

with the constants:

days	Length1	L $\infty$	a	b	kc	kd	ke	kf	kg
42	5	38	-0.0344	-0.0249	0.00297	-0.0000604	9.32E-08	-5.79E-13	5.57E-08

Water temperature data (temp) were calculated for each month using mean daily water temperatures over the given period of gauged records at Fitzroy River at The Gap (130005a) (Appendix A). Temp2 was the square of these values.

For each IQQM scenario (Pre-development, Current Development, Full Development), flow data were summed to give total freshwater inflow to the estuary for the period between dates when each cohort was sampled (flow0). There was a possible delay between the timing of a freshwater flow event and subsequent effects on the growth rates of banana prawns (i.e. a lagged effect) as a consequence of nutrient input and trophic transfer. To include potential lagged effects in the model freshwater flows were aggregated for the four weeks prior to the first sampling date of a cohort (flow4). Three daily time series of fortnightly banana prawn growth were generated.

A threshold of concern (ToC) could not be applied as the link between banana prawn growth, survivorship and abundance has not been quantified. Therefore only the likelihood of water resource development potentially affecting banana prawn growth was assessed for each season and on a yearly basis using growth frequency duration graphs and as a proportional change between scenarios.

## **Results**

There was a significant reduction in juvenile banana prawn growth between pre-development and development scenarios, with percent deviation ranging from -11% to -30% (Table 23). There was little reduction in growth between the two development scenarios. Summer growth was the most effected, followed by spring, winter and autumn.

The greatest deviation of banana prawn growth occurred between the 0.75 to 2.5 mm/week growth, with a maximum deviation of 20% time exceedence at 1 mm/week growth (Figure 26). Banana prawn growth outside of this range varied little between scenarios.

**These results indicate that the value of Banana prawn growth in the Fitzroy WRP area is potentially at higher risk under both development IQQM scenarios evaluated.**

**Table 23: Total percent deviation of average weekly *Penaeus merguensis* growth (green shading 0% to ±5%; yellow shading ±5% to ±15%; orange shading ±15% to ±25%; red shading >±25%)**

## 4.5 Offshore reef fisheries

### Methods

The method used to identify potential risk to offshore reef fisheries in response to changes in flow regime is based on research undertaken by Platten & Sawynok (2008). This study examined the catch records of two fishing clubs fishing in three locations; the Wanderers Fishing Club (Cape Capricorn and Gladstone Harbour) and Yaralla Fishing Club (Capricorn Bunker Group of the Great Barrier Reef). The long term datasets of catches (1976 to 2008) from two recreational fishing clubs were used to develop predictive numerical models of fisheries response (through catch rates) to river flow.

The results from the Capricorn Bunker Group were used in this investigation. The catch is multi-species but dominated by the Redthroat Emperor (*Lethrinus miniatus*). The initial analyses showed that catch rates increased, in response to increased river flows, especially above a flow threshold of greater than mean wet season flows. It also indicated that catch rates remained elevated for several years after large flow events. There may also be a limit to the positive correlation between flow and catch rate, as there is little increase in catch rates once flows exceed a certain level as circled in Figure 27 (Platten & Sawynok, 2008).

Figure 27: Time series of catch rates (fish/person/trip) and wet season flow (ML) of the Fitzroy River at the Gap gauging station (Platten & Sawynok, 2008)

Based on these analyses numerical models consisting of two parts were developed (Platten & Sawynok, 2008). The first model was a logistic equation and included all years, apart from those following high flow years, and was of the form:

$$\text{Catch rate} = f / (a + b \cdot e^{-((m(\text{wet season flow}) + c)/g)}) + d$$

with the constants:

a	b	c	d	f	m	g
12120.44	3312455.74	-210028.55	16.53	190548.16	1.08	1083205.75

Due to the lagged effect demonstrated, the second model included years following above average wet season flows (Figure 29) and was of the form:

$$\text{Catch rate following high flow year} = 0.6473(\text{catch rate in high flow year}) + 4.0969$$

The models provided a good representation of the data (Figure 28 and Figure 29), with the logistic curve and linear equation describing 78% and 89% of the variance, respectively.

**Figure 28 : Modelled (triangles) and observed catch rates for the Great Barrier Reef site compared with wet season flows of the Fitzroy River. Solid vertical line represents mean wet season flow; dashed line represents median wet season flows.**

**Figure 29: Modelled relationship between catch rates the year following above average wet season flows and the catch rates of years with above average flows for the Capricorn Bunker Group**

Each equation was applied to respective wet season IQQM modelled data (Pre-development, Current Development, Full Development) to generate three daily time series of annual offshore reef catch rate. A threshold of concern (ToC) could not be applied as the effect of time between high catch years has not been quantified. Therefore only the likelihood of water resource development potentially affecting the number high catch years was assessed as a proportional change between scenarios. The time series of catch rates was also examined to determine potential differences on the number of years between high catch years (i.e. spell analysis of non-high catch years).

## Results

The numbers of high catch years at the Capricorn Bunker group decreased by five years (12% deviation) between pre-development and development scenarios (Table 24). The maximum number of years with consecutive high catch rates were seven years from 1905/06 to 1911/12 and 1973/74 to 1979/80 (Appendix G; Figure 30). The maximum spell length between modelled high catch years for all scenarios was 16 years from 1923/24 through until 1938/39. The next greatest spell between high catch years was from 1992/03 to 2006/07, where 15 years passed without modelled high catch rates. During this period there were three years where high catch years were predicted to occur.

**These results indicate that the chances of high catch years at the Capricorn Bunker are potentially reduced and the spell length between high catch years are increased under both development scenarios evaluated.**

**Table 24: Total percent deviations of offshore reef fisheries (Capricorn Bunker Group) high catch years (green shading 0% to ±5%; yellow shading ±5% to ±15%)**

## 4.6 *Polydactylus macrochir* (King Threadfin Salmon)

### Methods

*Polydactylus macrochir* (King threadfin salmon) are widely distributed throughout northern Australia, occurring in tropical waters from Northern Territory/Western Australia border to Noosa River (Queensland). King threadfin are a long lived species, living up to 14 years (Garrett, 1997), but more commonly to 11 years (Halliday *et al.* 2007a). King threadfin are protandrous hermaphrodites, beginning life as a male, changing into females and completing their entire lifecycle in estuarine and associated marine foreshore environments. Most King threadfin reach spawning maturity between two to five years and change from male to females between six and ten years (Robins *et al.* 2007). Spawning occurs in high salinity waters, from winter to spring, however timing varies between 'northern' and southern' Queensland stocks.

The research conducted by Halliday *et al.* (2007a) is the only documented study linking freshwater flows and King threadfin populations. This study provided quantitative evidence to support that there are substantial benefits to King threadfin production from allowing freshwater flows to reach the estuary. Evidence is seen in increasing catch, which represents enhanced King threadfin growth as a result of increased biological productivity within estuaries. Juvenile King threadfin benefit from increased biological productivity, as lowered salinities in favourable habitats affect the energy budgets and/or create turbid conditions which, in turn, reduce the threat of predation (Halliday *et al.* 2007a) (Table 18).

The outcomes of this study were utilised to identify risk to King threadfin population's growth and recruitment in both the Fitzroy and surrounding estuaries. The results of this study and general information about King threadfin in the Fitzroy estuary were discussed during a meeting with Dr Ian Halliday (DPIF Senior Fisheries Biologist). As a result of this meeting the recruitment model developed in Halliday *et al.* (2007a) was provided such that it could be applied to IQQM modelled datasets (see below).

The recruitment model uses the age-structures of the commercial catch collected over five consecutive years in the Fitzroy estuary to determine year class strength (YCS) of King threadfin (Halliday *et al.* 2007a). In total 716 King threadfin were aged using sagittal otoliths during the five consecutive 'sampling years' (year-1 = 2000/01, year-2 = 2001/02, year-3 = 2002/03, year-4 = 2003/04 and year-5 = 2004/05). Sampling occurred twice each 'sampling year', once in the week(s) preceding October and then again in the week(s) in February. The King threadfin catch ranged in age from 1 year old to 19 years old, with 3.1% of the sampled catch aged as one year old, 86.3% of the catch aged between 2 and 11 and 10.6% of the catch aged between 12 and 19 years-old.

The standardised residuals from the catch-curve regressions were used to give an indication of relative YCS for King threadfin aged between 2 to 11 years old. When compared against summer flow, the year-class strength of King threadfin fluctuated and was significantly and positively correlated ( $p < 0.001$ ), however the goodness-of-fit was relatively low ( $R^2 = 0.3488$ ) (Figure 17; Figure 31). The resulting linear equation was applied to log<sub>10</sub> summer (December-

February) IQQM modelled data (Pre-development, Current Development, Full Development) to generate three yearly time series of YCS.

A threshold of concern (ToC) was defined to establish the consequence of altering YCS on King threadfin populations. A theoretical relationship between YCS and population maintenance was calculated using the thresholds described in Halliday *et al.* (2007a) where strong (>0.5 YCS index), moderate (0.5 to -0.5 YCS index) and poor (<-0.5 YCS index) years were identified. The proportional change between scenarios was calculated to identify changes between years of strong, moderate and poor YCS.

Strong recruitment years were considered to be those required to maintain a sustainable King threadfin population and the greater the number of years between these events, the higher potential risk to King threadfin populations. A high risk profile (i.e. potential local population failure) was defined as any year where the number of consecutive years without strong recruitment exceeded the most common longevity of King threadfin, 11 years. A moderate risk profile was defined as any year where the number of consecutive years without strong recruitment was between the minimum age of protandry of six years (Robins *et al.* 2007) and the high risk profile. All other years were deemed as being low risk to King threadfin populations. Overall risk from water resource development was interpreted as a change in the risk profiles (i.e. relative proportion of each risk category) between the pre-development scenario and the two development scenarios.

**Figure 31: Scatter plot of catch-curve regressions of king salmon against summer freshwater flows from the Fitzroy River estuary.**

## Results

Assessment of the pre-development scenario revealed that more than 7 out of 10 years contained flows which would result in moderate King threadfin recruitment (Table 25). Of the remaining years, 17% were modelled as strong years and 11% as poor recruitment years.

Comparisons between pre-development and development scenarios revealed a decrease in strong and moderate recruitment years and a substantial increase in poor recruitment years (Table 25). Deviation between current and full development scenarios remained relatively unchanged for strong or moderate recruitment years, but increased in poor recruitment years. Most differences between IQQM scenarios were between 0.3 to -0.8 YCS regression residuals (Figure 32), with the greatest deviation occurring around the -0.3 YCS where a 16% deviation in time exceedence was observed.

Risk to King threadfin persistence from water resource management varied between pre-development and development scenarios, with an increased risk to King threadfin persistence in development scenarios (Figure 33). There was little change in risk profile between current and full development scenarios. Over half (56%) of the pre-development years were within the low risk profile, whilst 42% of years were low risk in the development scenarios. There was little difference between scenarios in the moderate risk category which accounted for 26% (pre-development) to 29% (current development and full development) of the total modelled years. The risk to King threadfin YCS was greatest in the development scenarios, with 29% of the modelled years at high risk compared to 17% for the pre-development scenario.

**These results indicate that the value of a persistent population of King Threadfin in the Fitzroy WRP area is at higher risk under the development scenarios evaluated.**

**Table 25: Total percent deviation of *Polydactylus macrochir* Year Class Strength (YCS) for strong, moderate and poor recruitment years (green shading 0% to ±5%; yellow shading ±5% to ±15%; orange shading ±15% to ±25%; red shading >±25%)**

## 4.7 Riffles as habitat

### Methods

Riffles are generally the most productive of riverine habitats, supporting a complex diversity of plants (e.g. macrophytes and benthic algae, fungi and bacteria) and animals (e.g. macroinvertebrates, fish, reptiles and amphibians). Riffles are often covered in many obligate and sometimes rare and sensitive rheophilic taxa (i.e. taxa which only occur in flowing water) specially adapted to cope with the fast flowing conditions. Their occupancy is primarily due to higher dissolved oxygen concentrations (caused by water turbulence), high availability of food resources (due to a concentration of drifting food such as invertebrates and detritus and rheophilic prey), improved level of light penetration (due to shallow water levels) and higher nutrient supply through groundwater/surfacewater connectivity.

Riffles are often cited as habitats at high risk due to flow modification (DNR, 1998 *WAMP TAP Technical Report 4*), and are sensitive to too little or too much flow. The worst case scenario is a complete loss of riffles through either drowning out of riffles or the complete cessation of flows. This would almost certainly result in a localised extinction of the obligate rheophilic taxa. Riffles are more commonly altered through a change in the duration, timing and magnitude of flows and changes between spell duration and timing of dry/drown-out periods. The ecological impacts will vary depending upon the nature of change, and will be influenced by the natural/historic flow pattern (riffles that dry/drown out more often will have a community adapted to these conditions), local climatic conditions (the more severe the dry/drown out period the greater the impact to the ecology) and location relative to recolonisation sources (the closer the recolonisation source, the less likely impact).

The method undertaken to identify potential changes to flows affecting riffles is summarised below in Figure 34 and uses rheophilic aquatic macroinvertebrate taxa as indicator species. The method uses riffle macroinvertebrate data and velocity and depth profiles at riffles associated with IQQM nodes. A percent riffle inundation rating curve is created whereby modelled flow data can be applied and a daily time series of percent riffle inundation created for each IQQM scenario.

Longitudinal and cross-sectional survey data were gathered from 13 riffles associated with WRP and IQQM nodes (Figure 35). In June 2008, five cross-sections and one longitudinal section were surveyed at nine sites in the Dawson River, Nogoia River and Theresa Creek. No surveys were conducted in the Mackenzie and Fitzroy Rivers as all riffles visited were flooded due to releases from upstream dams and weirs, and mine water releases. Survey data stored in Hydstra and collected as a part of the first Fitzroy WRP were used at these sites, (Figure 35).

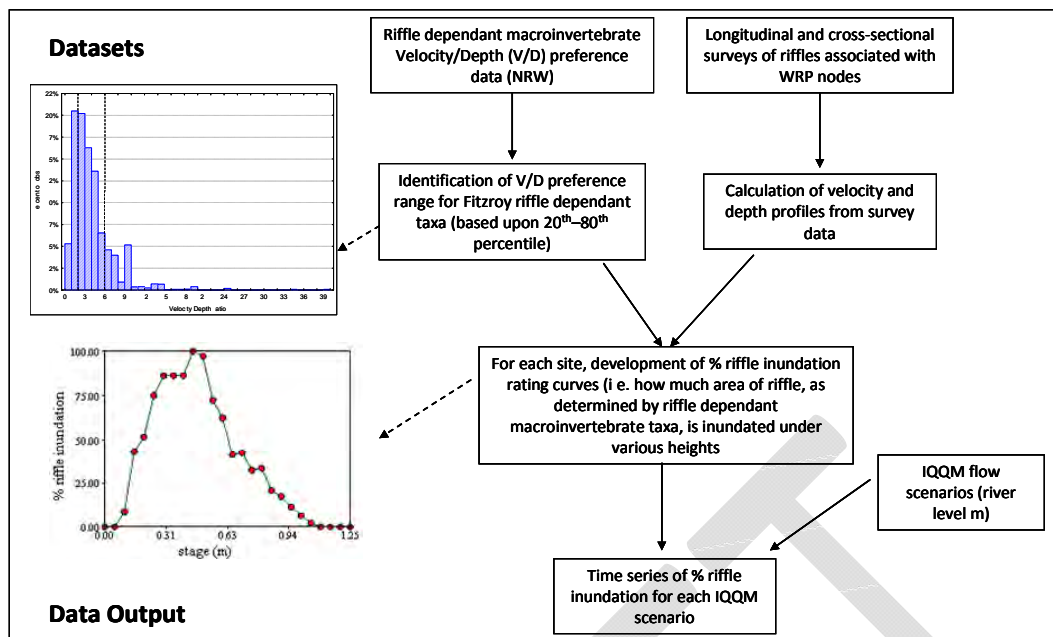

Figure 34: Flow diagram of the process undertaken to develop a % riffle inundation models

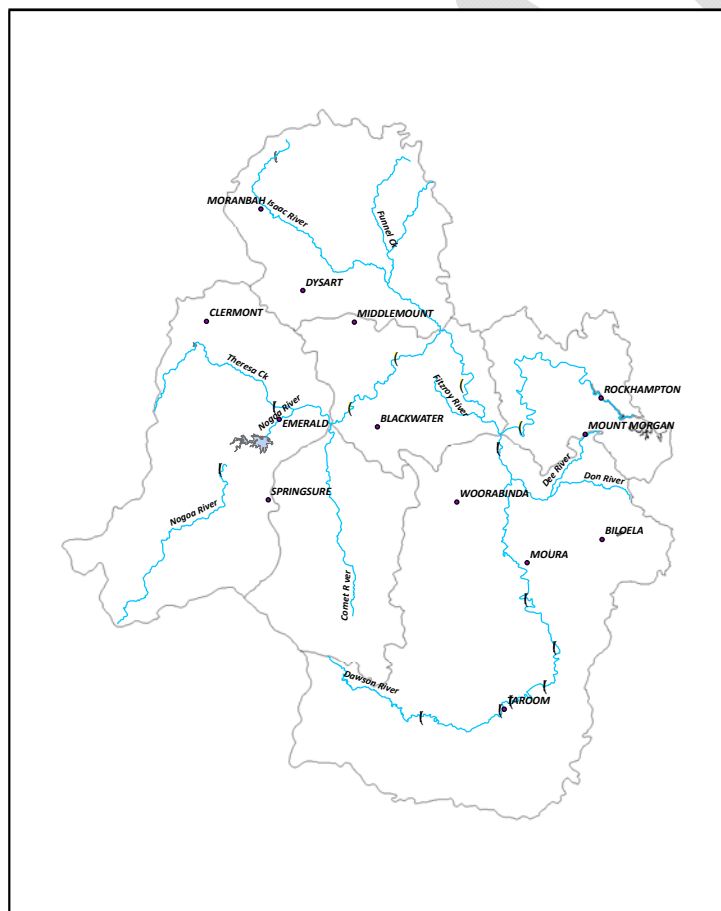

Figure 35: Location of riffles assessed as a part of this review. Black circles indicate sites surveyed during June 2008; Yellow circles indicate site survey data accessed through the DERM Hydstra database.

The Slope/Area method was utilised to calculate water depth and velocity profiles at cells along the riffle cross-sections (Bird, 1992). The method, based on Mannings Equation, uses river slope (m/m) and riverbed roughness (Mannings n) to estimate the hydrological parameters of the riffle cross-section, including discharge, surface area, relative water height and velocity.

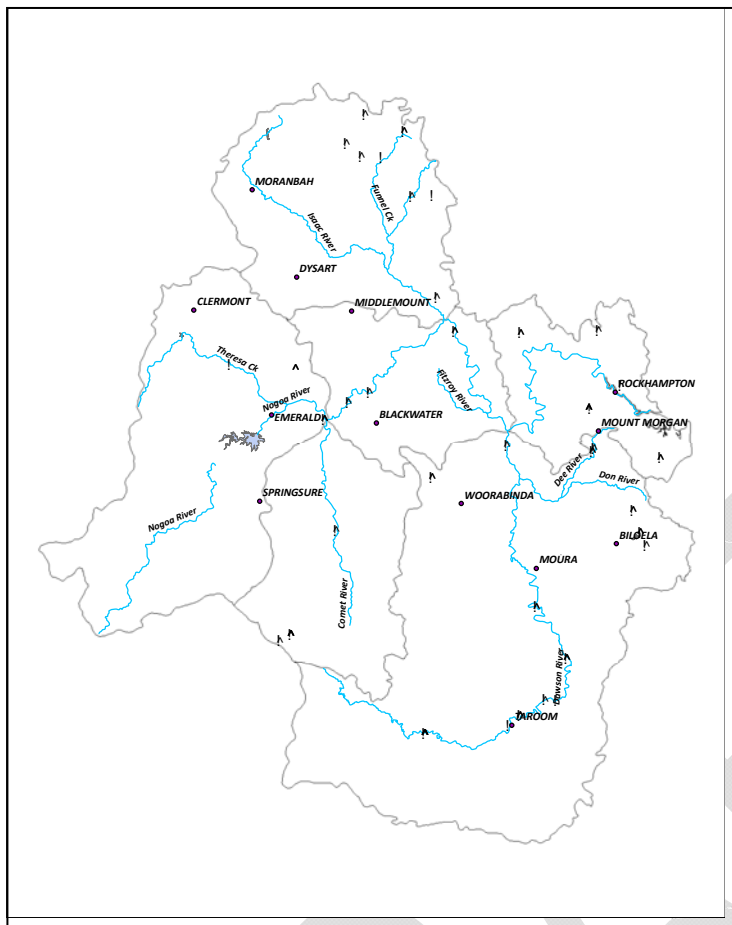

Figure 36 demonstrates how velocity and depth data were calculated for each riffle. At any given water height, velocity, depth and width were estimated at a number of intervals ('cells') across the riffle cross-section. Estimates were undertaken at 0.05 m intervals from 0 m to 2 m river height, whilst the number and width of 'cells' across the cross-section was irregular and determined by changes in riverbed height. At each 'cell' velocity/depth ratio (V/D) was calculated for further assessment. All analyses were undertaken in RATE1 (v1.1) computer software and exported and edited in Excel©.

**Figure 36: Riffle cross-section demonstrating how water depth and velocity parameters were calculated across riffle cross-section profiles.**

A habitable riffle was determined using preference ranges of rheophilic macroinvertebrate taxa collected as a part of the DERM Statewide macroinvertebrate biological monitoring program and Fitzroy WRP pilot monitoring program (Figure 37). Marshall *et al.* (2000) identified macroinvertebrate flow preferences for all taxa collected from around the state and identified 22 rheophilic taxa. Of these 18 were found to occur in the Fitzroy Basin, with 14 taxa occurring at or near sites associated with WRP nodes.

The V/D preference range was calculated for all 14 rheophilic taxa based upon the 20th to 80th percentile range of occurrence. From a total of 731 samples, V/D ratio's ranged from 0.05 to 40, with the 20th to 80th percentile from two to six (Figure 38).

**Figure 37: Location of riffles sampled for macroinvertebrates as a part of the DERM biological monitoring programs (1994-present) and WRP pilot monitoring project (2003-2004).**

**Figure 38: Frequency analysis of the velocity/depth ratio for 14 rheophilic macroinvertebrate taxa found in the Fitzroy Basin. Dashed lines indicate the 20th (V/D=2) and 80th (V/D=6) percentiles.**

Each 'cell' V/D ratio identified in the cross-section survey analysis was assessed against the macroinvertebrate V/D preference range. For any given river height, the width of each 'cell' within the macroinvertebrate preference range (V/D 2-6) was summed to provide an estimated width of habitable riffle across the riffle cross-section. The percent riffle inundation rating curve was created for each riffle when performed for all 0.05 m river heights between 0-2 m.

Each rating curve was converted to a percentage of the maximum % riffle inundation value and imported into the Rating Curve function of the River Analysis Package (RAP Version 2.0.4; eWater (2008)). These were applied to each of the three IQQM scenarios (scenarios back-calculated to height (m)) to generate three daily time series of % riffle inundation for each node. This was summarised across the entire simulation period to highlight broad differences between the pre-development and each of the two development scenarios.

A threshold of concern (ToC) could not be applied as the specific flow duration requirements of rheophilic macroinvertebrate taxa are largely unknown. Therefore only the likelihood of water resource development potentially changing the frequency and duration of flow events was assessed for each site and across the plan area. The total percentage of time as a habitable riffle, dry riffle and inundated riffle was assessed as a proportional change between scenarios. The average duration and frequency between riffle forming flow events was assessed as a proportional change between scenarios.

## **Results**

The percent of time when riffle forming flows occurred varied considerably around the basin, with values in the pre-development scenario ranging from 27% (Bingegang) to 90% (Baroondah) (Table 26). The remaining time was mostly dry, with values in the pre-development scenario ranging between 5% (Baroondah) and 58% (Bingegang). The percent of time where the riffles were drowned out did not exceed 22%.

With the exception of one site (Dawson River at Isla Delusion), the percent of time where flows maintained habitable riffles decreased from pre-development to development scenarios, with the current development containing the least number of days (Table 26). The sites where most deviation was modelled included Dawson River at Woodleigh, Dawson River at Boolburra, Mackenzie River at Coolmaringa and Mackenzie River at Bingegang. In most cases the full development scenario increased the number of days when compared against the current development scenario, particularly at the Dawson River sites. The reduction in habitable days stems from an increase in the number of dry periods and a decrease in the number of days where the riffles were drowned.

In the pre-development scenario, the average duration of riffle forming flows ranged from 15 (Bingegang) to 67 (Baroondah) days, with an average of 29 days (Table 27). With the exception of one site (Isla Delusion), a reduction in average duration was modelled between pre-development and current development scenarios, with the Dawson River at Boolburra and

Dawson River at Woodleigh displaying the most reduction. A similar pattern was modelled between pre-development and full development scenarios, with the exception of Dawson River at Woodleigh which experienced a significant increase in riffle duration.

The average spell length between riffle forming flows was significantly lower than riffle duration, with an average spell length ranging between 7 and 17 days (Table 27). Individual nodes experienced both increases and decreases in spell length across the simulation period with percentage deviation from the pre-development case ranging from -183% to 34%. In most instances this equated to less than five days difference. In the full development scenario for Dawson River at Isla Delusion and Dawson River at Woodleigh there was a three-fold increase and decrease in spell length, respectively.

**These results indicate that the value of riffles as habitat in the Fitzroy WRP area is potentially at higher risk under the development scenarios evaluated.**

## 4.8 Waterholes as refugia

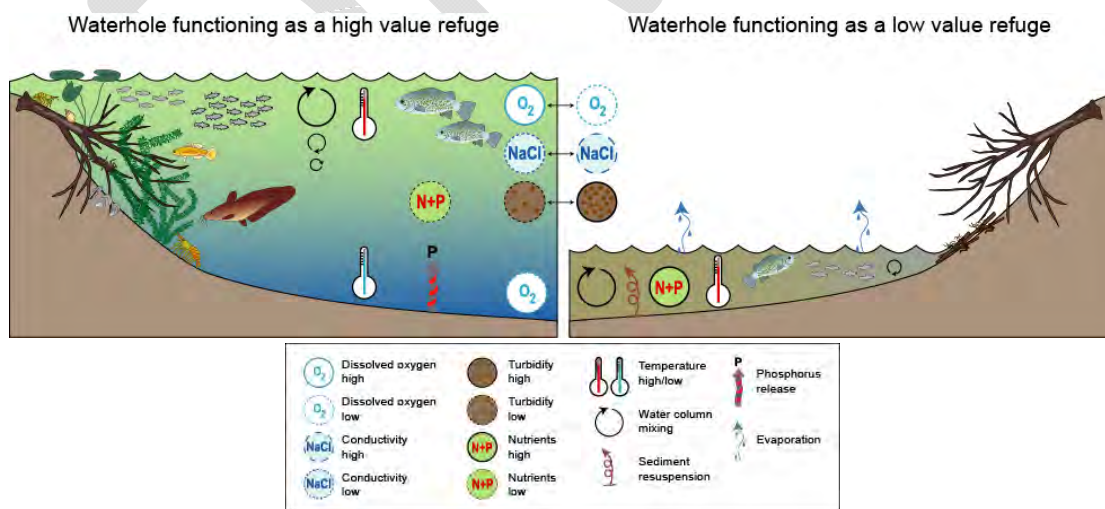

### Methods

The Fitzroy River experiences a tropical to sub-tropical, subhumid to semi-arid climate, dominated by summer rainfall, and high rainfall variability (Nix 1977). As a result stream flow is also variable, with flow ceasing in many areas for most of the year (Gunn 1977, Kelly 1996) and the system contracting to a series of disconnected in-channel pools termed waterholes. During periods of rainfall, disconnected waterholes are replenished and re-connected.

These waterholes provide the primary source of surface water during dry periods and are particularly important for riverine biota because they provide drought refuge. This allows species to persist through these otherwise harsh conditions. For obligate freshwater species (those entirely restricted to freshwater for their entire lifecycle), waterhole refugia are absolutely essential for their long term survival.

The persistence of a waterhole (i.e. the period of time that a waterhole can retain water) determines the maximum time it can function as a refuge. As such, estimating persistence is the first step in understanding and managing refugial waterholes. Despite their obvious importance and the increasing pressures from climatic and anthropogenic sources, few studies (e.g., Costelloe *et al.*, 2007), have attempted to estimate waterhole persistence.

The drying out of waterhole is not the sole mechanism by which waterholes can lose their function of supporting aquatic biota. Loss of habitat quality is equally important (Figure 39). As the depth of water remaining in a waterhole decreases the amount of habitat available to support biota also decreases and the quality of the water diminishes. These processes pose a threat to the survival of biota living in the waterhole.

**Figure 39: Changes in waterhole habitat quality due to decreasing depth**

Biota that rely upon waterholes as refugia are fragmented into local populations within waterholes during times without flow. These local populations suffer extinction whenever an individual waterhole dries or becomes unsuitable in some other way. Such events naturally occur in dryland river systems. The survival of species within dryland river catchments depends upon the number of waterholes that continue to function as refugia during dry times and repopulation of the system following reconnection. Therefore, the number of waterholes simultaneously losing the ability to support local populations can be used as an estimate of risk to the viability of catchment-wide populations of aquatic species.

Waterhole depth was modelled for 14 waterholes within the Fitzroy WRP area (IQQM flow nodes used for each site are listed in Table 28) by firstly conducting surveys and developing digital elevation models and secondly by modelling water loss in the absence of flow and other water inputs. The latter was based on SILO Data Drill lake evaporation rates. These models were then applied to IQQM scenarios to calculate daily estimates of waterhole depth. When there was flow at the waterhole (based on an IQQM scenario) waterholes were considered to be full. Once flow ceased the waterhole model was invoked.

**Table 28: Waterhole persistence modelling sites and associated IQQM flow nodes**

Waterhole	Closest Node	
	IQQM Number	IQQM Name
Boolburra	na	End Dawson
Burke	na	Inflow Eden Bann

Koch	na	Inflow Eden Bann
Pelican	na	Inflow Fairbairn
Reilys	11	Carnangarra
Riversleigh	na	Inflow Eden Bann
Taroom	6	Taroom
Waddington	4	Woodleigh

Time-series of waterhole depth were analysed to estimate two aspects; the frequency and duration of empty waterhole spells and the frequency and duration of spells below the ToC. There have not been any studies of these phenomena in the Fitzroy to enable an empirical ToC to be set. Therefore a ToC of 0.5 m below cease to flow was adopted to reflect the current cease to flow threshold in the Fitzroy WRP. Occurrences of simultaneous spells across multiple waterholes were used in both cases to estimate risk to the function of refugia resulting from the three IQQM scenarios.

## Results

Of the 14 waterholes studied, only one completely dried during the model simulation period (Pelican Waterhole) and this occurred under all three IQQM scenarios indicating there is no increased risk to the system from water management in this regard.

When the Threshold of Concern (ToC) of 0.5 m below cease to flow was applied to the IQQM scenarios there was some, minor change between the pre-development case and the two development cases (Figure 40 and Figure 41). Under the current development case simultaneous breeches of the ToC occurred on nine occasions as a result of flow management. The durations of these breeches were generally weeks to months and ranged from approximately 14 to 80 days (see Table 29 and Appendix H). For the full development case there were six such occasions and the breeches ranged from approximately 15 to 63 days. It should also be noted that in both cases the development for some individual waterholes (e.g. Reilys Waterhole) prevented water levels dropping below the ToC when they were modelled to do so under the pre-development case.

Figure 40: Percentage of days over the simulation period that the depth of each waterhole was modelled to fall below the ToC for the three IQQM scenarios.

Figure 41: Duration of the longest spell when the depth of each waterhole was modelled to be below the ToC for the three IQQM scenarios.

**Table 29 : Summary of number of spells and spell length that each waterhole was below 0.5M cease to flow level. Probability of below ToC is the proportion of days out of the simulation period that the water level of was below the ToC (0.5m CTF).**

	Current Development	1.260%	220	124.500	4
	Full Development	0.000%	na	na	0

Because the deviation from the pre-development was very minor, they made very little difference to the risk profile of waterhole habitat across the plan area (Figure 42). There were no high risk events (i.e > 75% of waterholes with simultaneous depths less than the ToC) under any of the three scenarios. Almost all of the time there was low risk under all scenarios with moderate risk (50% to 75% of waterholes with simultaneous depths less than the ToC) occurring less than 1% of days under the two development scenarios and never under the pre-development scenario.

**These results indicate that values associated with waterhole persistence and habitat in the Fitzroy WRP area are not threatened by either of the two development scenarios evaluated.**

Figure 42: Potential risk profile of waterhole habitat across all sites.

## 4.9 Wetlands

### Methods

It is estimated that there are over 14,300 wetlands occurring in the Fitzroy Basin, comprising of estuarine (64%), riverine (21%), palustrine (8%) and lacustrine (7%) wetlands. This includes a World Heritage Area (Great Barrier Reef), a Ramsar listed Internationally Important Wetland (Shoalwater and Corio Bays Area), 20 Nationally Important Wetlands (Directory of Important Wetlands in Australia (DIWA)) and numerous unlisted local and regionally significant wetlands (EPA, 2009).

The ecological significance of wetlands of the Fitzroy Basin can not be underestimated. They support a diverse range of plants and animals; provide habitat and refuge for many migratory and threatened species; play an essential role in natural hydrological cycles and act as a filter against nutrients and sediments. There are over 360 wetland indicator species recorded in the Fitzroy Basin; 22 of which are listed as rare, endangered or threatened species (EPA, 2009). Many of the wetlands, particularly including those of the Fitzroy River Floodplain and Delta, are recognised both nationally and internationally as important waterbird habitat. These and other wetlands of the Basin are also important fishery habitat (Sawynok, 2003; 2004; Sawynok

and Platten, 2005; Hyland, 2002). Many wetland biota are opportunistic; utilising resources when available and/or avoiding periods of unfavourable conditions.

Patterns of wetting and drying determine species diversity and richness (Boulton & Brock, 1999). Wetlands receive water from a variety of sources, including groundwater, overland flow, tributary inflow and the river. Whilst the relative importance of these water sources will vary between wetlands; wetland ecosystem functioning relies on the exchange of water, nutrients and biota between the river and wetland.

Estimations of flows that inundate different wetland features were made for the original WAMP process (Roberts, 1998). This report utilised modelling nodes to segment the basin, and characterised the flows required to inundate the basic features of the segment, such as main river channel (backwaters and waterholes), middle terraces (flood runners and smaller ephemeral wetlands), higher alluvial terraces (oxbow lakes, billabongs, lagoons and floodplain wetlands); and wetland features indicative of each segment.

The estimations of flows that inundate the indicative wetland features that have been used to query the IQQM are presented in Table 30. Not all indicative wetlands are tabulated; rather only those under potential risk have been assessed. For each wetland the flow estimates were applied to its respective node for all three IQQM scenarios to generate three daily time series of daily flow above the inundation flow level. All analyses were undertaken in the River Analysis Package (RAP Version 2.0.4; eWater (2008)).

A threshold of concern (ToC) could not be applied as the specific ecological requirements of the taxa inhabiting the wetlands are largely unknown. Therefore only the likelihood of water resource development potentially changing the frequency of wetland inundating flow events was assessed for each wetland across the plan area. Likelihood was measured through the proportional change of percent daily exceedence above inundation flow levels and the average spell length between these events.

**Table 30: Wetland features of the Fitzroy Basin included in the assessment and the corresponding flow magnitudes that are necessary to inundate each wetland.**

River	Feature	Flow ML/day	IQQM Node

## Results

The percent of daily exceedence above wetland filling thresholds varied considerably around the basin, with values in the pre-development case ranging from 0.10% (Lake McDonald) to 7.05% (Duckponds lagoon (LHB)) (Table 31). The majority (8 out of 14) of the wetlands had less than 1% daily exceedence above the wetland filling threshold.

With the exception of one wetland (Eurombah Crossing), the percent of daily exceedence above the filling thresholds decreased from pre-development to development scenarios (Table 31). The degree of variation between pre-development and current development ranged from -40% to 0%, with most (12 of 14) having percent variation less than -13%. The exceptions to these were the Duckponds Lagoons (both left and right hand banks) where -37% and -40% deviations were modelled.

The full development scenario further reduced the days above the filling threshold (Table 31). Wetlands where there was further significant reduction in the days above filling flows include Yeppen Lagoon, Frogmore and Woolwash lagoons, Bears Lagoon/Maloney Creek, Isla Delusion floodplain and Boam Creek anabranche. This reduction in filling flows was most apparent at Dawson River sites.

The average spell length between filling thresholds varied around the basin, with values in the pre-development case ranging from 99 days (Duckponds lagoon (LHB)) to 2815 (Lake McDonald) (Table 31). There was an increase in spell length for both development scenarios, with the degree of variation varying from 0% to 80%. For the current development scenario, the sites most affected included Duckponds Lagoons (both left and right bank). In the full development scenario there was an increase in spell length for the majority of sites, with those most affected including Bears Lagoon/Maloney Creek, Isla Delusion floodplain and Boam Creek anabranche.

**These results indicate that the value of wetlands as habitat in the Fitzroy WRP area is potentially at higher risk under the two development scenarios evaluated.**

## 4.10 Flow spawning fish species

### Methods

The ecological assets which relate to the flow spawning fish species guild include the Fitzroy Golden Perch (*Macquaria ambigua orientalis*), Black catfish (*Neosilurus ater*), Hyrtl's catfish (*Neosilurus hyrtlii*) and Leathery grunter (*Scortum hillii*). A model-based risk assessment approach was used to compare the relative risk to Fitzroy Golden Perch population viability from water resource development scenarios. Fitzroy Golden Perch is a long-lived, flow-spawning fish species. Its complex environmental flow dependencies are relatively well known from a combination of population surveys and expert observations and knowledge. As such, Fitzroy Golden Perch was considered representative of other assets with similar life history requirements.

A population viability analysis was conducted utilising a suite of population models that take biological information about a particular species (i.e. habitat requirements, birth and death rates, population size, etc.) to make predictions about future population sizes. This was modelled using a dynamic Bayesian Belief Network (BBN) simulation and a projection model to simulate temporal and spatial processes including migration, and quantify population viability over space and time. As well as changes to the flow regime, the analysis takes into account barriers to fish migration which plays a critical role in recruitment and re-colonisation. Details of the modelling and assessment approach are given in Menke *et al.* (2009).

### Results

Clusters of nodes emerge in the basins mid-elevation streams, where the Golden Perch population is most affected (Figure 43). These zones of higher impact on the population are located near dams and weirs, which hinder or block Golden Perch migration, and are separating parts of the lower catchment and the upper catchment, which are less affected by development. The impacts of pre-development and current development scenarios, and also the full development scenario including the Nathan Dam project, can be clearly distinguished and ranked by the analysis (Figure 43).

The model produces quantitative results based on existing population estimates. Thresholds of Concern (ToC) for the population are identified with the help of estimates of minimum viable population size from international-level research.

**Figure 43: Frequency of node failures per node during the simulation period for pre-development, current development and full development scenarios.**

The relative change in population survival probabilities from the pre-development to both development scenarios is shown in Table 32. All changes resulting from the development scenarios are reductions, but some, shown in green, are insignificant.

The results of this dynamic projection model are shown in terms of the number of simultaneous node failures in Figure 44. None of the development scenarios are reaching the Threshold of Concern regarding the viability of the Golden Perch population.

**Table 32: (Total) Percent deviation of Fitzroy Golden Perch population survival between development scenarios (green shading: decrease to 5 %, red shading: > 30 %).**

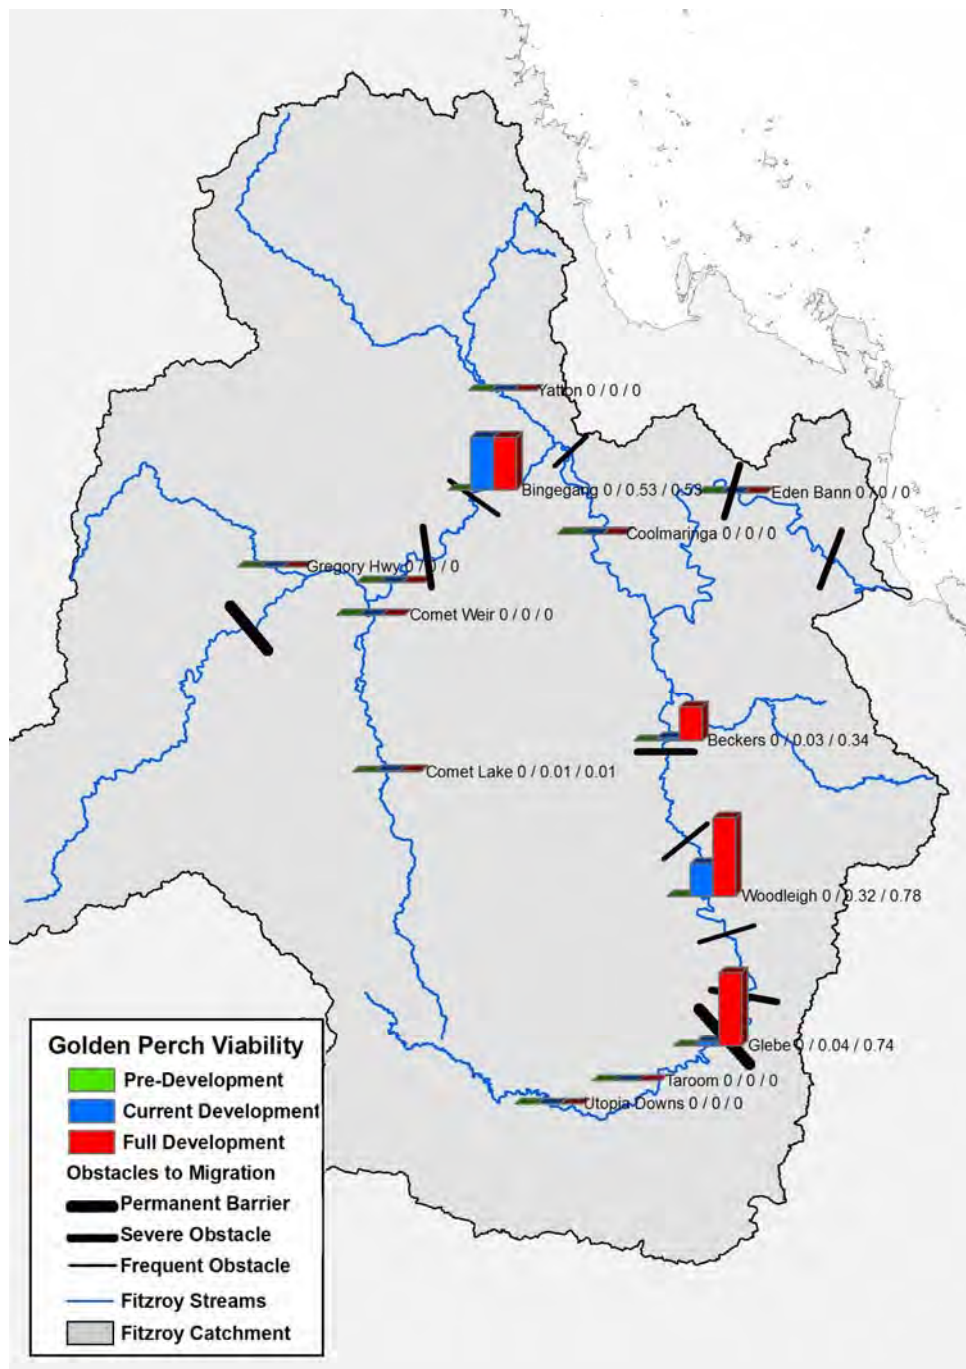

**Figure 44: Frequency of joint failures of populations during the simulation period for predevelopment, current development and full development scenarios.**

The spatial relationship between the sub-populations is clearly shown in Figure 45. The spatial relationship of severely affected nodes to dams & weirs is obvious for Woodleigh and Bingegang under the current development scenario and for Glebe with the proposed Nathan Dam project under full development. A construction of Nathan Dam is shown to affect additional nodes downstream (Woodleigh and Beckers). These sites are in close proximity to each other on the middle Dawson River, therefore the ability of these sites to be repopulated from neighbouring, unaffected sites is limited if local extinctions occur at sites affected by barriers to migration. Bingegang is the only node representing the heavily developed upper part of the Mackenzie River, and also shows a higher rate of population viability failure.

**These results suggest that the value of a persistent population of Fitzroy Golden Perch in the Fitzroy WRP area is at higher risk under the two development scenarios evaluated.**

DRAFT

**Figure 45: Pattern of population viability of Golden Perch for the reporting nodes in the Fitzroy basin. This is a relative assessment between all three scenarios, and the taller the bar, the higher the probability of local extinction. None of the nodes experienced any extinctions under the pre-development scenario. Black bars represent weirs and dams. The proposed Nathan Dam is shown as a barrier at Glebe.**

## **5. Discussion**

The risk assessment of ecological assets for the Fitzroy WRP and their potential risk trajectory under development scenarios are summarised in Table 33.

### **5.1 Ecological assets at low risk**

Five of the 14 assets were assessed at low risk, with the majority of these (four) being low flow assets. Stable flow conditions necessary for spawning of low flow spawning fish (glassfish, purple spotted gudgeons and rainbowfish) was generally similar between predevelopment and development scenarios. The modelled development scenarios therefore represent a low risk to the spawning of these species. For some sites (e.g. Beckers, Woodleigh, Bingegang weir and Fairbairn Dam) the flow conditions under the development scenarios were more stable and therefore provided more spawning opportunity. It is likely that a combination of factors resulted in more spawning opportunity at these sites e.g. continual water releases from Fairbairn Dam and the occurrence of small naturally occurring freshes at Woodleigh and Beckers.

Similarly, risk to waterholes was assessed as low. Most of the waterholes tested were large and occurred in the supplemented water supply area where water releases from upstream storages maintain water levels. One point worth considering is that only two unsupplemented waterholes were assessed (i.e. Taroom and Pelican). Waterholes in unsupplemented areas are potentially at higher risk as they are relatively small and do not receive the top-up flows that waterholes in water supply schemes receive. Pressure on these waterholes is further increased from extraction by water allocations granted pre-WRP, as they are not bound by the current 0.5m drawdown limit. Future assessments of waterholes located outside water supply scheme areas should therefore be undertaken.

Juvenile barramundi growth decreased under the development scenarios; however the magnitude of change was small. This suggests that the magnitude of flows under the development scenarios represents low risk to juvenile barramundi growth.

**Table 33: Summary of ecological assets potential risk trajectory under the development cases. Upward arrow represents an increase in risk; downward arrow represents a decrease in risk; circles represent no change in risk profile.**

Location		Low flow assets					Medium-High flow assets		High-flood flow assets

## **5.2 Ecological assets at higher risk**

All of the remaining assets were under higher risk; however the degree of potential risk varied both within and between asset groups.

The only low flow asset potentially at higher risk was riffles as habitat. Overall, potential risk for the measured indices (i.e. % time as habitat, % time dry, % time drowned, average duration of flows and average duration between spells) could be considered as moderate; however there were significant differences between sites. Sites upstream of the water supply scheme remained generally unchanged (e.g. Taroom and Baroodah). In the Nogo/Mackenzie and Dawson rivers potential risk increased with downstream distance, with Boolburra, Woodleigh and Bingegang the most affected. Risk also increased at sites affected by the proposed Nathan Dam. Most of the changes between scenarios resulted from an increase in the frequency and duration of dry periods, which is likely to be a result of changes in the flow regime through storage releases. However, the risk to the riffle community remains unknown, and the consequence of these changes require further investigation.

The two medium to high flow assets, flow spawning fish and riparian vegetation communities, were assessed at higher risk. The findings of the Fitzroy golden perch Bayesian modelling suggested that, under the current development scenario, the population is mostly affected in the middle sections of the catchment. Future developments represent a greater risk, particularly in the middle to lower Dawson River below the proposed Nathan Dam. Population status needs to be confirmed with additional monitoring and research, and management of connectivity of all parts of the basin's river network should be considered a high priority for long-term maintenance of the fish population.

Riparian vegetation communities, of which Coolabahs were the indicator species, were mostly at higher risk at sites directly downstream of major water infrastructure. In the current development scenarios, this included Bridge Flat Road and Bingegang, both of which are downstream of Fairbairn Dam. In the full entitlement scenario, most changes to the flooding opportunity also occurred at Woodleigh and Isla Delusion (downstream of the proposed Nathan Dam). Very large flood events (i.e. floods above the 75% inundation threshold) were the least affected, whereas those below 25% threshold were the most affected. Weirs were found to have very little influence on the flooding of riparian vegetation communities.

Alterations to the riparian vegetation community structure as a result of less flooding frequency are expected and future research should focus on potential consequences. The spell duration between floods will possibly have the greatest influence on the riparian community structure, with different species exhibiting different responses. Longer lived species, such as Coolabahs, are more likely to be able to persist with an extended flooding frequency; however recruitment would be affected. Shorter lived species may not be able to withstand extended spells between floods and population viability would be compromised.

Wetland flooding downstream of major water infrastructure was also assessed to occur less frequently under development scenarios. Under the current development scenario, this

included the Duckponds wetlands which is located downstream of Fairbairn Dam. The Duckponds (RHB) wetland had the highest potential risk, with the spell between flooding events almost doubling from filling every 1½ years to over 3 years. Under the full entitlement scenario the flooding frequency at sites downstream of the proposed Nathan Dam were also compromised; however with a less severity. Alterations to wetland communities are possible and future research should focus on potential consequences.

Notwithstanding these results, compensatory environmental flows may not be practical, if at all possible, for riparian vegetation communities and wetlands. Major flow events provide the only means of flooding as discharge capacities of the major infrastructure, including Fairbairn Dam, are not large enough to provide the necessary flooding flows. The provision of large flow events is an important consideration in the development of environmental flow management strategies for proposed water infrastructure (e.g. Nathan Dam and Connors River Dam).

Barramundi populations were assessed at higher risk. The work undertaken on Fitzroy estuary barramundi populations is the most extensive in Australia, with over 23 years of supporting data. Thus the results of this assessment are compelling. Both barramundi year class strength (i.e. years when barramundi were most spawned) and recruitment into nearby 12 Mile Creek were strongly linked to flow and risk was increased under both development flow scenarios.

Risk to the king threadfin salmon year class strength were also increased under the development flow scenarios; however natural risk was also assessed to be relatively high. Under pre-development conditions, about 17% of years resulted in low threadfin recruitment; this significantly increased under the development scenarios to approximately 30% of years.

The only fully marine asset assessed, offshore reef fisheries of the Capricorn Bunker Group (Great Barrier Reef), were assessed to be at potentially higher risk under both development scenarios. The chances of high catch years were assessed to be potentially reduced and spell length between high catch years increased.

For the development scenarios, reduction in wet season flow volumes during periods of naturally occurring low flow, and thus an extension of low flow periods, were the primary cause for the increased risk profile of barramundi, threadfin salmon and offshore reef fisheries, with each asset having between 2 to 4 high risk periods over the 107 modelled sequences (Figure 46 to Figure 49). In most instances, these high risk periods were not present in the pre-development scenario where the sequences were interrupted by years where flows provided the necessary recruitment conditions. During extended periods of low flow, low storage volumes and a high demand for waterharvesting is expected, which would reduce the volume of water reaching the estuarine/marine systems. Given that these flows are very important for securing existing water entitlements, it is not expected that compensatory environmental flows during these low flow periods would be possible.

This increased risk to barramundi, threadfin and reef fisheries populations must be considered in a wider context, as their persistence is influenced by a variety of activities. A recent assessment of the barramundi fishery in Queensland suggested that the fishery is dangerously overfished (Campbell *et al* 2008). Habitat quantity and quality along the coastal and floodplain regions have also been affected through extensive development of ponded pasture systems, barriers to floodplain and upstream movement and invasion of weed species (Cotterell & Jackson, 2000; Hyland, 2002). Potential climate change is also expected to decrease barramundi recruitment (Sawynok & Platten, 2008). Given these pressures, it is important that the allocation and management of streamflows in the WRP protects the volumes and frequency of medium to high flows discharged into the Fitzroy estuary and surrounding freshwater and marine environments.

**Figure 46: Modelled total wet season flows (November to March) for the Fitzroy Barrage, with the periods of high risk to 12 Mile Creek barramundi populations highlighted. Circles represent times during the high risk period where flows were recruitment flows were provided under the pre-development scenario.**

**Figure 47: Modelled total wet season flows (December to February) for the Fitzroy Barrage, with the periods of high risk to barramundi year class strength highlighted. Circles represent times during the high risk period where flows where recruitment flows were provided under the pre-development scenario.**

Circles represent times during the high risk period where flows where recruitment flows were provided under the pre-development scenario.**

**Figure 49: Modelled total wet season flows (November to March) for the Fitzroy Barrage, with the periods of high risk to offshore reef fisheries highlighted. Circles represent times during the high risk period where flows were provided under the pre-development scenario.**

### 5.3 Future research priorities

#### Improving our understanding of Ecological Assets

The above assessments have highlighted that further research is required to improve our understanding of the ecological risk through water resource planning. A summary of these include:

- Low Flow Spawning Fish Species
  - assets identified at low risk; no further work is required
- Floodplain Riparian Vegetation Communities and wetlands
  - asset identified at higher risk
  - recommend that future studies be undertaken which assess the consequences of changes in flooding frequency on riparian communities and wetlands
- Barramundi, Offshore reef fisheries and Threadfin salmon
  - assets identified at higher risk
  - higher risk must be considered in a wider context, as their persistence is influenced by a variety of activities, including over fishing and habitat alterations

- the increased risk to recruitment needs to be assessed in terms of its potential consequences to the fisheries industry
- Banana Prawn
  - assets identified at higher risk
  - the increased risk to prawn growth needs to be assessed in terms of its potential consequences to the fisheries industry
- Riffles as habitat
  - asset identified at higher risk
  - risk to the riffle community remains unknown and the consequence of these changes require further investigation.
- Waterholes as refugia
  - asset identified at low risk
  - risk to unsupplemented waterholes not assessed in detail and requires further research
- Flow spawning fish species
  - asset identified at higher risk
  - population status needs confirmation and management of connectivity of all parts of the basin's river network may require a high priority for long-term population management

### **Ecological Risk Assessment methodology**

In addition to further research on assets, the ecological risk assessment methodology could be improved to include:

- the effects of barriers to longitudinal connectivity as risk may be underestimated if recolonisation processes are impeded by barriers to dispersal.
- details about how local populations rebound from adversity (or even local extinction), particularly as many high risk assets had long periods (up to 16 years) without receiving their critical water requirements.
- asset thresholds of concern are currently binary (i.e. pass or fail) whereas current research suggests that these functions follow a more sigmoidal curve. Ongoing research is required to develop more rigorous population models to derive these functions.
- a more transparent process of linking the asset risk back to the values associated with the ecological outcome. Acceptable levels of risk can then be assigned.

## Minister's foreword

The Fitzroy Basin Water Resource Plan released in 1999 was the first of its type for Queensland's developed coastal catchments. It broke new ground and opened a new chapter of awareness regarding the importance of integrated, sustainable resource management. As part of the renewal process a new water resource plan for the Fitzroy Basin must be developed to ensure we stay ahead of the game, learn from the lessons of the past ten years and look to innovative ways of addressing the challenges and opportunities that lie ahead.

The new draft water resource plan for the Fitzroy Basin has been released for public scrutiny to enable all stakeholders to have a say prior to finalisation. The process has been well-informed, with preparation of the new draft water resource plan supported by findings from hydrologic, environmental and socioeconomic technical assessments, along with input from the community. I would like to thank the groups and individuals who contributed to the process, in particular the Fitzroy Basin community reference panel members. I would also like to thank the previous Isaac Connors and Callide groundwater community reference panel members.

This overview report provides a plain English guide to the accompanying new draft water resource plan summarising key outcomes and provisions in the new draft plan, and the reasoning behind them.

The new draft water resource plan builds on the achievements of the existing plan and provides a balanced and sustainable approach to managing water resources in the Fitzroy Basin. The new draft plan includes strategies which provide for the management of groundwater for the first time, security for existing water users including the environment, establishment of additional tradeable water allocations, improved specification of entitlements and unallocated water reserves to support future development.

I encourage anyone with an interest in the water resources of the Fitzroy Basin to study this document and the accompanying new draft water resource plan and participate in the process by making a formal submission. All properly made submissions will be fully considered in finalising the water resource plan.

Stephen Robertson  
Minister for Natural Resources,  
Mines & Energy and Minister for Trade

## How to make a submission

Submissions are invited on the Draft Water Resource (Fitzroy Basin) Plan 2010 (new draft plan) which will replace the Water Resource (Fitzroy Basin) Plan 1999. Anyone can present a submission about the new draft plan.

### Submission form

The form on the next page can be used to lodge a submission about the attached new draft plan. Complete the five steps on the first page of the form to finalise a submission. Internet submissions will also be accepted.

An electronic submission form can be found at <[www.derm.qld.gov.au/wrp/fitzroy.html](http://www.derm.qld.gov.au/wrp/fitzroy.html)>.

Completed submission forms should be forwarded to the following address:

Postal address	Street address
Department of Environment and Resource Management	Department of Environment and Resource Management
Attention: Kel Roberts	Attention: Kel Roberts
Central West Region Water Services (Fitzroy Basin WRP)	Central West Region Water Services (Fitzroy Basin WRP)
P O Box 1762	Level 2 209 Bolsover Street
Rockhampton Qld 4700	Rockhampton Qld 4700

### Submissions may also be made via:

Email: [wrpfitzroy@derm.qld.gov.au](mailto:wrpfitzroy@derm.qld.gov.au).

Fax: (07) 4938 4011 Attention: Kel Roberts

### For further information on submissions:

Telephone: 1800 822 100

### Closing date for submissions

All submissions must be received by **5.00 pm on 28 February 2011**.

# Submission form

## Draft Water Resource (Fitzroy Basin) Plan 2010

### Please use a ballpoint pen to complete this submission

Submissions are being sought from interested individuals and groups about the content of the Draft Water Resource (Fitzroy Basin) Plan 2010 (new draft plan).

The Minister for Natural Resources, Mines and Energy and Minister for Trade has released the new draft plan for public review, discussion and submissions. Submissions will be considered by the Minister in finalising the Fitzroy Basin Water Resource Plan.

Please complete the following five steps to make a proper submission:

- On the form, enter the name and address of each person making the submission.
- Ensure that each person making the submission has signed it.
- State the grounds of the submission, and the facts and circumstances relied on in support of these grounds.
- If you require more than the space provided in this submission form, please attach this completed submission form as a cover sheet to your detailed submission and tick the 'Detailed submission attached' box on this submission form.
- Ensure your submission is lodged by **5 pm on 28 February 2011**.

# Summary

## Purpose of the overview report

This overview report, a requirement of the *Water Act 2000* (the Water Act), has been prepared to accompany the release of the Fitzroy Basin Draft Water Resource Plan (new draft plan). The finalised new plan will replace the expiring Water Resource (Fitzroy Basin) Plan 1999 (Fitzroy WRP 1999).

The overview report summarises the development and provisions of the new draft plan including differences from the Fitzroy WRP 1999. It also outlines the main issues raised by the community and the results of technical assessments prepared to provide information for the development of the new draft plan.

The overview report provides interested agencies, groups and individuals with supporting information that will promote understanding of the new draft plan. It will also assist those intending to prepare a formal submission. The minister will consider all properly made submissions prior to finalisation of the new plan.

## Developing the new draft plan

Water resource plans, are subordinate legislation. The *Statutory Instruments Act 1992* provides for renewal of subordinate legislation after 10 years to ensure it is 'relevant to the economic, social and general wellbeing of the people of Queensland and ... of the highest standard'.

In line with the requirements of the Water Act, the provisions of the new draft plan were developed by evaluating and balancing the many factors—hydrologic, environmental and socioeconomic—that influence how water is allocated and sustainably managed to meet present and future needs.

Preparation of the new draft plan began formally in June 2008 through public notification and release of an information report that explained the renewal process and outlined key issues pertinent to the plan area.

Submissions on the proposed new draft plan were invited, and a community reference panel comprising representative Fitzroy Basin stakeholders was formed. Although the panel was not a decision-making body, it played a key role in advising the minister on water-related issues and community water needs and aspirations for the region.

In December 2008, the minister announced his intention to amalgamate the new water resource plan process with the Isaac–Connors and Callide groundwater amendments to the Fitzroy WRP 1999. The notices of intent for the groundwater amendments were released in December 2006 and they had progressed to the extent that technical studies were undertaken and planned community reference panel (CRP) meetings completed. Amalgamation enabled more efficient use of resources and provided an easier and more transparent public release process. Submissions on the amalgamated notice of intent were invited and one submission was received. That submission was considered together with submissions received on the initial notice of intent for the new draft plan and submissions received on the notices of intent for the Fitzroy WRP 1999 groundwater amendments.

In developing the new draft plan many factors were considered to provide a sound basis for the finalisation and implementation of a new plan. These factors include:

- effectiveness of the strategies contained in the Fitzroy WRP 1999 and implemented through the Fitzroy Basin Resource Operations Plan (Fitzroy ROP)
- existing water entitlements, works and their use
- hydrologic, environmental and socioeconomic factors raised in the technical assessments including changes in water demand and risks to natural ecosystems
- future water needs including cultural, economic and environmental water needs over the life of the new plan
- inclusion of subartesian water
- emerging issues such as climate change and water quality
- community views and aspirations as raised in public submissions and during community reference panel meetings.

By reviewing and assessing relevant information in this manner and utilising advances in scientific knowledge the new draft plan has been developed to provide a balance between the water needs of the environment and future community water requirements.

## Key provisions of the Fitzroy WRP 1999

Generally the Fitzroy WRP 1999 provided for:

- regulation of water in a watercourse, lake or spring and overland flow water
- environmental flow objectives (seasonal base flow, first post-winter flow and medium to high flow) based on a hydrologic model with a simulation period from 1900 to 1995. All allocation and management decisions must be made in accordance with the objectives which ensure the maintenance of stream-flow variability and seasonality
- ecological and cultural values of waterholes and lakes by imposing a 0.5 metre draw down limit on new entitlements with an exemption for stock and domestic take.

For existing entitlements the Fitzroy WRP 1999 provided for:

- full use of existing entitlements and continued use of existing overland flow works
- establishment of supplemented water allocations in the Dawson, Nogoia Mackenzie, Lower Fitzroy and Fitzroy Barrage water supply schemes
- establishment of unsupplemented water allocations along the Nogoia, Mackenzie, Comet and Fitzroy rivers, although water allocations have yet to be established in the Fitzroy ROP for the Comet River
- water allocation security objectives based on a hydrologic model with a simulation period from 1900 to 1995
- amendment of some existing entitlements to include conditions, volumetric limits and maximum rates of take.

For future development, the Fitzroy WRP 1999 provided for:

- additional unallocated water to meet future water demands while maintaining water flows to support environmental processes and protecting existing entitlements
- unallocated water reserves in some water supply schemes
- an unallocated water reserve for the Nathan Dam project (up to 190 000 ML/a) on the Dawson River
- provision for dealing with unallocated water.

For overland flow water, the Fitzroy WRP 1999 provided for:

- continued use of existing works to capture overland flow water and authorisation of new overland flow works for stock and domestic purposes, to meet the requirements of an environmental authority, to contain potentially contaminated agricultural run-off, to divert water around a mine site and small scale storages up to 5 ML capacity
- authorisation of the take of overland flow water for other purposes e.g. irrigation, following the notification of such existing works within 12 months of the commencement of the Fitzroy WRP 1999
- a requirement for a water licence to take water (from release of unallocated water) and development permit for new overland flow works
- a requirement for new works, including authorised works, to be constructed in accordance with provisions of the *Sustainable Planning Act 2009* and associated codes. An exemption was provided for activities authorised under a mining tenement and the *Petroleum Act 1923* or *Petroleum and Gas (Production and Safety) Act 2004* until the Fitzroy ROP was amended to include overland flow
- continuing the effect of the moratorium on new works to take or store water taken from a watercourse that may increase the take of overland flow water, until an amendment is made to the Fitzroy ROP in relation to overland flow.

For monitoring and reviewing purposes, the Fitzroy WRP 1999 provided for:

- monitoring by the resource operations licence holder and the state, including stream flow, water quality, aquatic ecosystems and water use to establish how effectively the plan's outcomes are being achieved
- preparation of an annual report on the plan by the minister that summarises monitoring, new research findings, and assessments of the effectiveness of the plan's strategies in achieving its outcomes
- a mechanism for the minister to consider amending the plan if there is a major change in circumstances relating to water demands or environmental water need.

## Key provisions in the new draft plan

The new draft plan will continue and build on the provisions mentioned above and the major provisions include the following:

For the environment:

- keeping the long-term total flows downstream of the Fitzroy Barrage to above 77 per cent of mean pre-development flows as per the existing Fitzroy WRP
- specification of environmental flow objectives that will ensure the continued application and improvement of seasonal base flow and first post-winter flow management strategies
- limitations and additional criteria for dealing with future applications to interfere with the flow of water by impoundment to minimise any impacts arising from in-stream barriers
- allocation and flow management strategies that will support good water quality outcomes.

New provisions for the management of groundwater:

- the regulation of subartesian water with specific management arrangements in five groundwater management areas
- strategies to address the over-allocation and overuse of groundwater in the Callide Valley alluviums, including a reduction in groundwater entitlement volumes from 37 375 ML to a sustainable level of about 19 000 ML
- improved management of groundwater in the Isaac–Connors and Don River subcatchments and continued use of existing groundwater works in the currently undeclared areas. This would be subject to a notification of works process and subsequent granting of water licences
- improved volumetric specification of existing groundwater entitlements, through the amendment of licences not being converted to water allocations. Amendments would occur as required, to include a purpose, an annual volumetric limit and conditions
- licences to take groundwater for stock purposes in the Callide groundwater management area will no longer be required
- additional take of groundwater will generally be subject to the future release of specified reserves of unallocated water.

Key provisions for more secure water entitlements and expanded opportunities for water trading:

- transitioning of existing water allocations to the new plan
- specification of water allocation security objectives to ensure appropriate long-term security for both established and new water allocations
- establishment of tradeable water allocations to take supplemented surface and groundwater in the Callide Valley Water Supply Scheme
- establishment of tradeable water allocations to take unsupplemented groundwater in the Callide Valley alluviums
- establishment of additional water allocations to take unsupplemented surface water in the Nogoia River, Dawson River, Comet River, Theresa Creek and Retreat Creek areas
- improved volumetric specification of existing surface water licences, through the amendment of licences not being converted to water allocations. Amendments would occur as required, to include a purpose, maximum rate, daily volumetric limit, annual volumetric limit and conditions. A monthly volumetric limit may also be required on some water licences.

Continued management of overland flow water, subject to the following changes:

- the size of overland flow storages that can be used for any purpose without the need for a water licence will be increased from the current 5 ML to 50 ML.
- mines will be required to notify existing overland flow works within 12 months from the commencement of the new plan.
- exemptions that existed for mining operations to take overland flow for consumptive purposes without the requirement for a water licence will be removed to ensure a consistent regulatory approach for all users.
- limiting the areas covered by the continued effect of the moratorium on new works to take or store water taken from a

watercourse that may increase the take of overland flow water, until an amendment is made to the Fitzroy ROP in relation to overland flow. This provision would now only apply to specific parts of Theresa Creek, Retreat Creek and the Comet River systems.

- authorising any incidental take of overland flow water associated with the storage and subsequent beneficial use of coal seam gas water.

Key provisions to support future development:

- reserves of unallocated surface water totalling 301 900 ML/a that provide for water infrastructure projects including the Connors River Dam (56 400 ML/a), Nathan Dam (90 000 ML/a) and Lower Fitzroy storages (76 000 ML/a), as well as providing for future demands for state, Indigenous and general purposes in other parts of the plan area
- provision for Nathan Dam on the Dawson River is changed from up to 190 000 ML/a for primarily irrigation purposes to 90 000 ML/a for high security supplies such as for mining, urban and power generation
- unallocated groundwater reserves totalling 16 200 ML/a for state and general purposes in those parts of the plan area that can sustain additional levels of groundwater use
- unallocated groundwater reserve of 20 000 ML/a from naturally saline water in the coastal parts of the Fitzroy groundwater management area for possible expansion of the salt production industry
- interim arrangements to provide access to unallocated water for state purposes prior to the future amendment to the Fitzroy ROP.

For monitoring and review of the plan—updated monitoring requirements including groundwater monitoring requirements have been included.

# 1 Introduction

## 1.1 Role of the overview report

Preparation of an overview report is required under the *Water Act 2000* (Water Act) to support the development of a water resource plan. This report is a companion document and guide to the Fitzroy Basin Draft Water Resource Plan (new draft plan), with which it is released. The overview report explains:

- how and why the new draft plan was prepared
- the factors considered in preparing the new draft plan
- the key provisions of the new draft plan and reasoning behind them including differences from the Water Resource (Fitzroy Basin) Plan 1999 (Fitzroy WRP 1999)
- the role of community consultation and technical assessments in the development of the new draft plan
- the process for finalising and implementing the new plan.

The report aims to:

- promote informed debate and understanding about the water planning process.
- provide interested agencies, groups or individuals with the information they need to prepare a formal submission on the new draft plan for the minister to consider prior to finalisation.

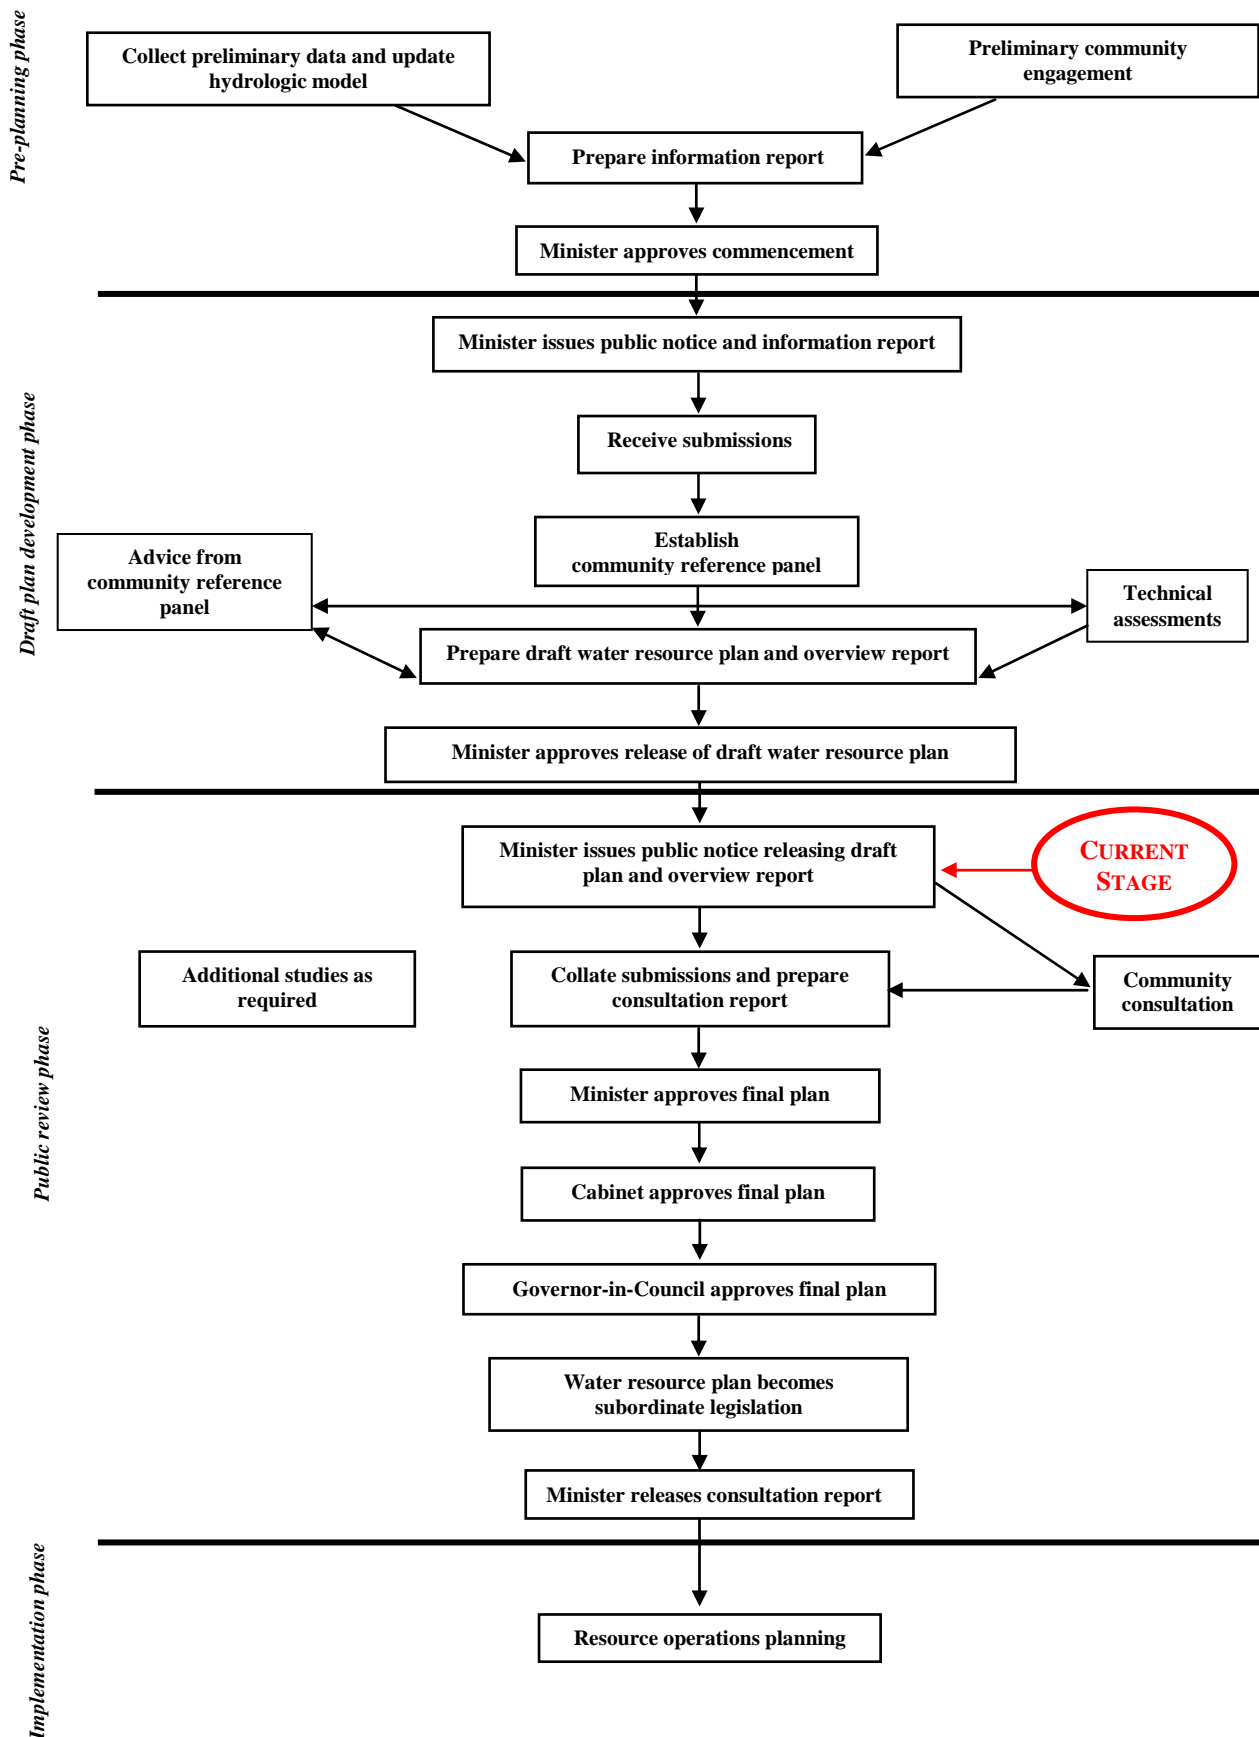

The report comprises seven chapters which address the following matters:

- Chapter 1 provides an introduction to the process and profiles the plan area
- Chapter 2 summarises the new draft plan purposes and outcomes
- Chapter 3 explains the strategies for achieving general and specific surface water and groundwater outcomes
- Chapter 4 explains the strategies for achieving ecological outcomes including specific ecological outcomes
- Chapter 5 outlines monitoring and reporting requirements
- Chapter 6 sets out arrangements for implementing and amending the plan
- Chapter 7 summarises how the new draft plan was developed.

The water resource planning process and the current status of its preparation are shown in Figure 1.

Figure 1: The water resource planning process

## 1.2 Background to the water resource planning process

In the initial stages of Australia's water resource development, the small population generated relatively negligible development pressures and the negative effects of unstructured and incremental water resource allocation policies were correspondingly low. In the latter part of the last century, as economic growth increased in Australia and the limitations on water availability became apparent, it was clear that a more coordinated approach to water allocation and management was needed to sustain future needs.

In addition to this, drought caused further stresses to some catchments which had previously not seen the effects of water supply limitations. These factors combined to drive the need for a new approach to water management, the focus of which was to strike a balance between environmental needs and socioeconomic needs of a catchment. This is an especially important consideration in a dry land, renowned for its extreme climatic variability.

### 1.2.1 Water reforms and the National Water Initiative

In 1994, the Council of Australian Governments agreed on a set of principles for restructuring water allocation and management approaches. The states and territories agreed to implement changes that would ensure water resource availability was properly assessed and supplies sustainably allocated to support economic, social and environmental needs.

As the water reform progressed the principles were refined under the 2004 National Water Initiative.

The new draft plan is consistent with Queensland's commitments to national water reform through:

- transparent, statute-based water planning
- better definition of terms and conditions for water entitlements
- providing for the conversion of water entitlements to water allocations and increasing opportunities for trading
- stating general and ecological outcomes
- allowing for potential future water demands to be met where sustainable
- ensuring that appropriate monitoring and reporting requirements are introduced to foster water user confidence and ensure that ecological outcomes are being met
- encouraging water use efficiency within the urban and rural sectors as a way of meeting increased water demands
- addressing currently over-allocated and/or overused systems
- recognition of the linkages between overland flow water and stream flows as complementary parts of a single surface water resource, including their management and allocation as a single resource
- recognition of the linkages between groundwater and stream flows as complementary parts of a single resource.

### 1.2.2 *The Water Act 2000*—the Queensland approach

Queensland's commitments to national water reform are principally met through the Water Act, under which the minister plans for the allocation and sustainable management of water through the preparation of a water resource plan for any part of the state. The requirements include provision for protecting natural ecosystems and security of supply for water users. A water resource plan can apply to water in streams, lakes and springs and, where necessary, to overland flow and groundwater.

### 1.2.3 The Fitzroy WRP 1999

Over the past decade, surface water in the Fitzroy Basin has been managed by the Fitzroy WRP 1999. This plan originally began as a water allocation and management plan but was transitioned under the Water Act to become a water resource plan. The Fitzroy WRP 1999 was amended in 2005 to include overland flow water.

The Fitzroy Basin Resource Operations Plan (Fitzroy ROP), which commenced in January 2004, implements strategies in the Fitzroy WRP 1999 by setting out the day-to-day arrangements to put these strategies into effect. The Fitzroy ROP has been amended, the most recent amendment occurring in July 2009. Overland flow water is yet to be included in the Fitzroy ROP.

While water resource plans can be amended or renewed at any time if the minister believes goals are not being met, are at risk, or if new economically viable uses emerge. A formal process for timely review and renewal is provided at 10-year intervals under the *Statutory Instruments Act 1992*. The Fitzroy WRP 1999 is now due for replacement by a new water resource plan.

## 1.3 A new water resource plan for the Fitzroy Basin

Through review and renewal, the new plan will be able to build on the achievements of the Fitzroy WRP 1999 whilst also responding to opportunities and challenges. Renewal enables a new plan to address water resource and use changes that have occurred during the past 10 years, including providing for the management of additional water resources not included in the first plan, as well as assessing the requirements for future growth and climate change.

Through the technical assessments that support development of the new draft plan, renewal provides the means for any new or improving knowledge that may be available to be appropriately incorporated into the new draft plan. Community consultation is also important so that community views and aspirations can be taken into account in the development of the new draft plan.

Preparation of the new draft plan began formally in June 2008, through public notification and release of an information report that explained the planning process and outlined key water resource management issues pertinent to the plan area. A supplementary public notice and information report were released in December 2008 to announce the amalgamation of the new plan process with the Callide and Isaac–Connors groundwater amendments to the Fitzroy WRP 1999 that commenced in December 2006.

The public notice announcing the release of the new draft plan is shown in Appendix A of this report.

### 1.3.1 The plan area and the water to which it applies

The Fitzroy Basin (plan area) is the largest coastal river basin in Queensland (Figure 2) and includes several extensive subcatchments that drain into the Great Barrier Reef World Heritage Area.

The new draft plan will continue to apply to:

- water in watercourses or lakes, including water in dams and weirs built across them
- water in springs not connected to artesian water<sup>1</sup>, and not connected to subartesian water<sup>2</sup> connected to artesian water
- overland flow water<sup>3</sup>.

The new draft plan will also apply to subartesian water (groundwater) for the first time.

---

<sup>1</sup> The Water Act defines artesian water as ‘water that occurs naturally in, or is introduced artificially into, an aquifer, which if tapped by a bore, would flow naturally to the surface’.

<sup>2</sup> The Water Act defines subartesian water as ‘water that occurs naturally in, or is introduced artificially into, an aquifer, which if tapped by a bore, would not flow naturally to the surface.’

<sup>3</sup> The Water Act defines overland flow water as ‘water, including floodwater, flowing over land, otherwise than in a watercourse or lake after having fallen as rain or in any other way or after rising to the surface naturally from underground.’

Figure 2: Map of the new draft plan area

CAS1752-1

### **1.3.2 Life of the new plan and new plan review**

Once finalised and approved, the new plan, as subordinate legislation to the Water Act, will expire after 10 years consistent with the *Statutory Instruments Act 1992*. Before its expiry, the minister must prepare another new water resource plan.

Should the need arise for minor changes the Water Act provides a process for amendments. The Act also provides a process for review and amendment should the need for more substantial changes arise.

An amendment to, or review of, the new plan could be triggered:

- if water entitlements in the plan area are unable to meet existing or emerging needs, having regard to potential gains from unallocated water available under the new plan, unused entitlements, water use efficiency improvements, or alternative water sources such as recycling
- if economically viable and ecologically sustainable uses for additional water are identified
- if the outcomes including ecological outcomes are not being achieved.

The new plan will primarily be implemented following an amendment to the Fitzroy ROP, as explained in Chapter 6 of this report.

## **1.4 Background to the Fitzroy Basin plan area**

The Fitzroy Basin covers approximately 142 600 square kilometres and is the largest coastal river basin in Queensland. A number of important river systems lie within the Fitzroy Basin, including the Dawson, Comet–Nogoa–Mackenzie, Isaac–Connors and Don–Callide river systems. The Fitzroy River has a mean annual discharge of approximately 5 941 000 megalitres, which flows into Keppel Bay south-east of Rockhampton. There are also important aquifers providing for groundwater extractions in the Fitzroy Basin, those of particular note being the alluvial aquifers in the Callide and Isaac – Connors subcatchments.

Major regional centres in the Fitzroy Basin are Rockhampton, Emerald, Moranbah and Biloela, while Mackay lies just to the north of the plan area and Gladstone to the south.

Due to its size and location, the Fitzroy Basin is diverse, encompassing a range of topographic and climatic regimes, from semiarid to subtropical. Rainfall, runoff and temperature are highly variable and irregular, and evaporation rates are high. Economic activities range from mining, manufacturing and agricultural production, to commercial fishing and tourism.

### **1.4.1 People in the plan area**

A number of regional councils lie within the boundaries of the Fitzroy Basin. The majority of the plan area is within the following councils:

- Rockhampton Regional Council
- Central Highlands Regional Council
- Banana Shire Council
- Woorabinda Aboriginal Shire Council
- Isaac Regional Council.

The plan area also incorporates small proportions of the following councils:

- Gladstone Regional Council
- Mackay Regional Council
- North Burnett Regional Council
- Roma Regional Council
- Dalby Regional Council
- Blackall Tambo Regional Council.

Australian Bureau of Statistics data indicate the estimated resident population of the plan area in June 2007 was 155 660 people. Rockhampton city accounts for approximately 42 per cent of the plan area population. The Australian Bureau of Statistics also estimates 5 per cent of the population identify themselves as being of Aboriginal and/or Torres Strait Islander origin. Indigenous people retain close social and cultural spiritual ties to the water and land of the region.

Department of Local Government, Planning, Sport and Recreation population forecast data prepared in 2008 indicate the resident population of the Fitzroy region<sup>4</sup> is expected to increase from an estimated 163 698 people in 2006 to almost 222 514 by the year 2026. Most growth is projected to occur in areas where there is mining.

According to the Australian Bureau of Statistic Census data in 2006, mining was by far the highest employing sector in the region, accounting for about 13 per cent of all employed persons. The agriculture, forestry and fishing sector is the fourth highest sector, accounting for 8 per cent of employment in the region. Employment in the mining and construction industries expanded dramatically between 2001 and 2006, highlighting the strong influence of the resources boom on the regional economy.

### 1.4.2 Industry in the plan area

The socioeconomic assessment (reports 1 and 2) conducted to support the planning process highlights the regional diversity of the plan area, and the importance of various water uses to the economy (see Chapter 7 for more information).

Water use supports a number of industries including mining and agriculture, as well as the urban sector. The main land use is grazing and main water use is irrigated cotton. Tourism and fishing (recreational and commercial) are also important to the plan area's economy. Adequate freshwater stream flows are important to the commercial and recreational fishing industries, as reduced stream flows can have an adverse impact on fish populations.

### 1.4.3 Ecological significance of the plan area

The Fitzroy Basin is home to significant fauna and flora that include migratory birds and numerous species of conservation significance listed under the Queensland *Nature Conservation Act 1992*. There are a number of species which may be affected by water management activities including the Fitzroy River turtle (*Rheodytes leukops*) currently listed as vulnerable<sup>5</sup>.

The Fitzroy Basin also contains a number of nationally important wetland areas listed in the Environment Australia Directory of Important Wetlands. Also, water from the Fitzroy Basin flows into the National and World Heritage listed Great Barrier Reef.

### 1.4.4 Water resource development and use

The plan area has five supplemented water supply schemes:

- Callide Valley Water Supply Scheme owned and operated by SunWater under an interim resource operations licence:
  - Major infrastructure: Callide Dam, Callide Weir and Kroombit Dam.
  - Total allocations: High priority (surface water) 4 311 ML, medium priority (groundwater) 19 527 ML and risk priority (surface water) 443 ML.
- Nogoia Mackenzie Water Supply Scheme owned and operated by SunWater under a resource operations licence:
  - Major infrastructure: Fairbairn Dam, Selma Weir, Bedford Weir, Bingeang Weir and Tartus Weir.
  - Total allocations: High priority 44 398 ML and medium priority 190 925 ML.
- Dawson Valley Water Supply Scheme owned and operated by SunWater under a resource operations licence:
  - Major infrastructure: Glebe Weir, Gylanda Weir, Orange Creek Weir, Theodore Weir, Moura Offstream Storage, Moura Weir and Neville Hewitt Weir.
  - Total allocations: High priority 5 579 ML, medium A priority 19 456 ML, medium priority 36 797 ML and an interim medium priority water allocation of 105 ML.
- Lower Fitzroy Water Supply Scheme owned and operated by SunWater under a resource operations licence:
  - Major infrastructure: Eden Bann Weir.
  - Total allocations: High priority 25 520 ML and medium priority 3 101 ML.
- Fitzroy Barrage Water Supply Scheme owned and operated by Fitzroy River Water (a business unit of the Rockhampton Regional Council) under a resource operations licence:
  - Major Infrastructure: Fitzroy Barrage.

---

<sup>4</sup> Includes Rockhampton (C), Emerald (S), Duaringa (S), Fitzroy (S), Livingstone (S), Peak Downs (S), Mount Morgan (S), Bauhinia (S), Banana (S), Taroom (S) and Belyando (S).

<sup>5</sup> Status under the *Nature Conservation Act 1992*

- Total allocations: High priority 50 483 ML and medium priority 11 610 ML.

Irrigation is the dominant supplemented water use (by volume) with the exception of the Lower Fitzroy and Fitzroy Barrage schemes where the principal use is industrial and urban.

In the Callide subcatchment mining, power generation and meat processing are significant water uses dependant on the Callide Valley Water Supply Scheme. Callide power station also imports water from Awoonga Dam in the adjacent Boyne River Basin.

The Fitzroy Basin also has three water management areas managed under the Fitzroy ROP:

- in the Nogoia Mackenzie and Fitzroy water management areas there are unsupplemented water allocations. See Section 3.2.2.1
- the Fitzroy WRP 1999 did not provide for conversion of unsupplemented authorisations in the Dawson Valley Water Management Area since operational details of the proposed Nathan Dam on the Dawson River were not then available.

Unsupplemented water authorisations outside these established water management areas continue to be managed under the Water Act and are subject to current terms and conditions specified on the authorisation. However, the Fitzroy ROP provided for amendment of some licences for consistency with the water resource plan and authorisations may also have been amended as a consequence of actions under the Act.

Unsupplemented subartesian water is used extensively throughout the Fitzroy Basin for urban, industrial, irrigation, stock and domestic purposes. The plan area is substantially covered by subartesian areas declared by regulation under the Water Act. These declared areas are listed in Schedule 11 of the Water Regulation 2002, together with the requirements for authorisation of entitlements and for assessment of works under the *Sustainable Planning Act 2009*. More specific management arrangements are contained in departmental policy and work practice documents.

There is currently a small percentage of the plan area where there are no requirements for managing or licensing of groundwater take. The amount of development in these areas is monitored by analysis of bore logs that are submitted as a mandatory requirement of licensed groundwater well drillers.

The Great Artesian Basin is located in the south-western part of the Fitzroy Basin and the Water Resource (Great Artesian Basin) Plan 2006 manages artesian water in this area.

## 1.5 Links with other planning initiatives

In recent years, the plan area has experienced a significant increase in natural resource management and planning activity as described below. To varying degrees, these initiatives have influenced the development of the new draft plan.

### 1.5.1 Central Queensland Regional Water Supply Strategy

The Central Queensland Regional Water Supply Strategy (CQRWSS), released in December 2006, is a non-statutory planning document developed by the Department of Environment and Resource Management (the department) in collaboration with other agencies, industry and community groups to inform long-term understanding of water supply and demand in the Central region. This included the identification of options for meeting projected future increases in demand through infrastructure and non-infrastructure options including water use efficiency and expansion of water trading. The new draft plan is consistent with the CQRWSS. In particular, proposed infrastructure mentioned in the CQRWSS is provided for under the new draft plan.

### 1.5.2 Central Queensland Regional Growth Management Framework

The Central Queensland Regional Growth Management Framework (released in 2002) was prepared by the Central Queensland Regional Planning Advisory Committee, in consultation with the communities of Central Queensland. It is the long-term regional planning strategy for Central Queensland. The framework is built around six guiding principles, one of which is in the area of resource use. That principle states: 'The allocation, use and management of the natural resources of Central Queensland shall be in accordance with the principles of ecologically sustainable development and shall be undertaken through the processes of integrated catchment management'. The new draft plan has been developed in alignment with the principles of sustainable development as required under the Water Act.

### 1.5.3 Reef Water Quality Protection Plan and the State Coastal Management Plan

The Reef Water Quality Protection Plan (Reef Plan), initially released in 2003 and updated in September 2009, is a joint initiative of the Australian and Queensland governments.

The Reef Plan identifies actions to halt and reverse the decline in the quality of water entering the reef, within a 10-year timeframe. The two primary objectives of the Reef Plan are:

- to reduce the pollutant load from non-point sources in the water entering the reef

- to rehabilitate and conserve areas of the reef catchment that have a role in removing water-borne pollutants.

The State Coastal Management Plan (coastal management plan), released in February 2002, is a statutory plan under the *Coastal Protection and Management Act 1995*. The coastal management plan provides the framework under which the coastal zone and its resources are managed. The coastal management plan includes objectives relating to water quality, Indigenous culture and the maintenance of coastal ecosystems.

The new draft plan is consistent with the principles of both of these plans. The strategies contained within the new draft plan maintain flows for the environment and will help to protect water quality. It also contains a number of strategies designed both to maintain processes that support coastal ecosystems and to support water-related cultural values of the traditional owners of the plan area.

#### **1.5.4 Environmental Protection Policy (Water) 2009**

The Environmental Protection (Water) Policy 2009 (EPP Water) is subordinate legislation to the *Environmental Protection Act 1994* and aims to protect Queensland's waters while allowing for development that is ecologically sustainable.

The purpose of the EPP Water is achieved within a framework that includes:

- identifying environmental values (EVs) for Queensland waters (including for aquatic ecosystems, water for drinking, water supply, water for agriculture, water for industrial and recreational use)
- deciding and stating water quality guidelines and water quality objectives (WQOs) to enhance or protect environmental values (EVs).

Draft environmental values and water quality objectives have been developed in collaboration with the Fitzroy Basin Association and key stakeholders and are being released for public consultation at the same time as the new draft water resource plan. The waters identified in the draft EVs report for high ecological value (HEV) level of protection are almost entirely within the protected estate and all these areas currently have near-natural flow regimes. In all catchments the aquatic ecosystem protection environmental value was recognised as important by the community. The defined environmental flow provisions of the new draft plan will continue to support aquatic ecosystem health and hence support draft aquatic ecosystem environmental values. Human-use EVs have also been identified across the catchment. The flow provisions of the new draft plan will continue to support the water quality required for EVs such as drinking water and irrigation.

It is important to note that while water resource plans can support good water quality outcomes, there are many other pressures on water quality that are external to water resource planning provisions. Such pressures include point source pollution, poor land use and management, and degradation of riparian vegetation and wetlands.

#### **1.5.5 Review of the Fitzroy River water quality issues**

In early 2008 the Premier of Queensland commissioned Professor Barry Hart to review water quality issues in the Fitzroy River after the discharge of over 138 000 ML of mine-affected floodwater from the Ensham Resources Pty Ltd coal mine located near Emerald in Central Queensland. Professor Hart released the report *Review of the Fitzroy River Water Quality Issues* in November 2008. The report contained one recommendation with a direct link to the Fitzroy Basin Water Resource Plan.

Recommendation 11: 'that DNRW consider a more equitable balancing of water between consumptive users and the environment, and the provision of State-owned contingency allocation, during the 10-yearly review of the Fitzroy Water Resource Plan'.

The Queensland Government released its response to Professor Hart's report and supported, or supported in principle, the report's 13 recommendations. In relation to recommendation 11, the government's response was: 'DERM will consider the balance between consumptive use and the environment, and the provision of a State-owned contingency allocation, in the current review of the Fitzroy Basin Water Resource Plan'.

Essentially Professor Hart recommended that the reservation of a large volume of water be held in storages (e.g. Fairbairn Dam) to respond to incidents that may affect water quality. Whilst the new draft plan does ensure an appropriate balance between consumptive use and the environment it does not provide for State-owned contingency allocations from major storages such as Fairbairn Dam. This is because:

- a State-owned contingency allocation would provide little or no benefit in mitigating water quality issues well downstream of any storage and would not assist with problems that may occur with water quality in unsupplemented streams
- it would be very expensive to acquire a significant allocation from an existing water supply scheme
- there would be impacts on the local economy since significant quantities of water would no longer be available for consumptive use.

Water quality outcomes are proposed to be achieved through other more effective means including by maintaining a flow regime and management strategies that mimic natural conditions and by including more responsive infrastructure operating rules in the Fitzroy ROP. Water markets will also provide a viable option for entities to acquire either permanent or temporary access to water supplies to support mitigation activity in response to any emerging or existing environmental or other situation.

### **1.5.6 Environmental Protection and Biodiversity Conservation (EPBC) Act 1999**

The *Environmental Protection and Biodiversity Conservation (EPBC) Act 1999* is the legislation which gives the Australian Government a framework for identifying and managing environmental assets of national significance. The environmental assessment prepared to provide information for the development of the new draft plan included consideration of the conservation status assigned to various environmental assets in the Fitzroy Basin. This also provided a basis for the Environmental Flow Assessment Program undertaken by the Department of Environment and Resource Management.

### **1.5.7 Central Queensland Strategy for Sustainability—2004 and Beyond**

The new draft plan builds on the work of the community-based natural resource management regional body in the plan area—the Fitzroy Basin Association (FBA). The regional body is responsible for preparing and implementing a natural resource management plan (NRM plan). The Central Queensland Strategy for Sustainability—2004 and Beyond (CQSS2) is the regional plan for the management of the natural resources and environments of the river catchments of the Central Queensland region. The plan guides investment strategies and seeks to protect the region's assets through addressing key pressures.

The NRM plan also assessed the condition of environmental assets in the Fitzroy Basin. There is some consideration in the document of economic and community viability with regards to these assets. As such, it formed a source of data for the environmental assessment for the new draft plan.

The new draft plan supports and builds on the objectives, outcomes and targets of the NRM plan by:

- protecting water ecosystem values and environmental conditions
- maintaining the current morphology and biodiversity of aquatic habitats
- promoting and allowing for sustainable water use to provide economic and social benefits to the community
- providing a more robust system of water allocation, reinforced by stronger licensing and monitoring of water use, leading to greater protection of water resources.

The new draft plan is consistent with the NRM plan and provides clear direction, supports environmental values, and promotes community and economic security and growth.

When finalised, the new plan will provide a statutory framework that supports the goals of the regional body and encourages efficient and sustainable water use.

## 2 New draft plan purposes and outcomes

The new draft plan following this overview report has been prepared and made available for public comment as required under the Water Act.

In addition to establishing a framework for sustainably managing and allocating water, the purpose of the new draft plan is to:

- define the availability of water in the plan area
- identify ways of and priorities for meeting future water needs
- provide for the creation of water allocations
- look to minimise, where practicable, degradation to natural ecosystems
- regulate the taking of overland flow
- regulate the taking of subartesian water (groundwater).

### 2.2 Plan outcomes

The Water Act requires that a draft water resource plan include its proposed outcomes. The outcomes are stated in Chapter 3 of the new draft plan and fall into four categories:

- general outcomes
- specific surface water and groundwater outcomes
- general ecological outcomes
- specific ecological outcomes.

Rather than being viewed as four separate categories, the outcomes should be seen as complementary and balanced set of responses for the sustainable management of the Fitzroy Basin's water resources.

The new draft plan outcomes, which reflect the diversity of issues raised through the community consultation process and technical assessments, guided development of strategies provided in Chapter 5 of the new draft plan.

#### 2.2.1 General outcomes

The new draft plan's provisions will cater for the area's consumptive and non-consumptive water needs for the 10 year life of the new plan. The general outcomes for the new draft plan are:

- to provide for the use of water entitlements and other authorisations in the plan area
- to provide for the continued use of existing overland flow works
- to provide for the continued use of existing groundwater works
- to protect the probability of being able to take water under a water allocation
- to support water-related cultural values including the values of the traditional owners in the plan area
- to provide mechanisms that support water being made available for the following:
  - population growth in towns and communities dependent on water resources in the plan area
  - growth in industries dependent on water resources in the plan area
  - stock or domestic purposes in the plan area
  - Indigenous communities dependent on water resources in the plan area to achieve their economic and social aspirations
- to support flexible and diverse water supply arrangements for consumptive water users
- to maintain flows that support water-related aesthetic, economic and recreational values in the plan area, including, for example, tourism
- to encourage continual improvement in the efficient use of water
- to provide a flow regime that supports the quality of water for human and ecological use.

The new draft plan's provisions will keep long-term total flows in the Fitzroy River downstream of the barrage above 77 per cent of mean pre-development flows as per the Fitzroy WRP 1999.

## 2.2.2 Specific surface water and groundwater outcomes

Specific outcomes have been included in the new draft plan for both surface water and groundwater. The specific surface water outcomes in the plan area make water available to support:

- mining and growth in the population of towns and communities, industry and agriculture in the Isaac-Connors, Upper Dawson and Lower Dawson subcatchments
- urban, industrial and other uses in the Fitzroy subcatchment.

The specific groundwater outcomes in the plan area relate to groundwater in the Callide Valley alluviums and provide for:

- the use of groundwater that can be sustained in the long term
- increased security for town water supplies and rural water supply boards that rely on groundwater
- security of supply for existing enterprises that rely on groundwater.

## 2.2.3 General ecological outcomes

The new draft plan's general ecological outcomes focus on making sure that water continues to move freely between habitats. These outcomes are summarised as follows:

- to minimise changes to the natural variability of flows that support aquatic ecosystems
- to provide continued connectivity between different parts of the river system
- to provide a flow regime that maintains delivery of fresh water to the estuaries of watercourses and the Great Barrier Reef Lagoon and supports productivity in the receiving waters of the Great Barrier Reef and inshore reefs
- to improve understanding of the matters affecting the flow-related health of ecosystems in the plan area
- to minimise the impact of the taking of water on aquatic ecosystems, including ecological assets
- to protect and maintain refugia associated with waterholes, lakes and wetlands
- to support surface water and groundwater interactions
- to support ecosystems dependent on groundwater including, for example, riparian vegetation and wetlands.

## 2.2.4 Specific ecological outcomes

The following specific ecological outcomes are included for areas of special note:

- to protect flows and water quality for flow spawning fish and endemic species e.g. the Fitzroy golden perch (*Macquaria ambigua orientalis*)
- to provide for flows necessary for estuarine ecosystem functions, including flows for:
  - barramundi (*Lates calcarifer*) and king threadfin salmon (*Polydactylus macrochir*) recruitment
  - banana prawn (*Penaeus merguensis*) growth
- to provide for groundwater levels to support relevant groundwater-dependent ecosystems and wetlands that rely on groundwater in the Callide Valley alluviums
- to maintain groundwater discharge to watercourses in the Isaac-Connors groundwater management area.

The strategies proposed in the new draft plan show how these outcomes are to be achieved. The strategies have been formulated to address issues raised during community consultation and in the technical assessments undertaken to provide a sound knowledge base from which to plan.

## **3 Strategies for achieving general and specific surface water and groundwater outcomes**

Surface water is currently regulated under the Fitzroy WRP 1999. The new draft plan proposes to continue the regulation of surface water and for the first time provide for the regulation of subartesian water (groundwater). The strategies contained in the new draft plan build on those contained in the Fitzroy WRP 1999 and address issues raised by the community, technical assessments and consideration of other emerging matters.

### **3.1 Continued use of existing entitlements**

#### **3.1.1 Surface water licences and overland flow works**

The new draft plan provides for the use of existing surface water entitlements. Riparian stock and domestic water use is authorised under the provisions of the Water Act without a requirement for a water licence. Additionally, the taking of water in an emergency situation, for example to fight a fire, is authorised under the Water Act. Existing overland flow works authorised under the Fitzroy WRP 1999 or built before the overland flow water moratorium in 2001 (subject to notification) will continue to be authorised under the new draft plan. See Section 3.5 for more information.

The new draft plan provides for better specification of existing surface water entitlements and conversion of additional existing water entitlements to unsupplemented water allocations in some areas. Existing licences not being converted to water allocations may be amended to include a purpose, maximum rate, daily volumetric limit, annual volumetric limit and conditions such as a passing flow requirement. Provision will be made for the inclusion of a monthly volumetric limit to support water sharing arrangements where necessary. See Sections 3.2 and 3.4 for further information.

Supplemented interim water allocations in the Callide Valley Water Supply Scheme (both groundwater and surface water) will be converted to surface water and groundwater supplemented water allocations. See Section 3.2.1.2 for more information.

Water resource plans provide an opportunity to bring historic and less than optimal management arrangements into line with the more contemporary arrangements provided for by the Water Act. Sections 82 and 83 of the new draft plan provides a process for granting licences to replace permits granted under the Water Act 1926 and a process to grant a licence to a mining lessee with a long historic take dating back to 1989.

#### **3.1.2 Groundwater licences and groundwater works**

The new draft plan will provide for the use of existing unsupplemented groundwater entitlements. In the Callide Valley alluvium, which is over-allocated, supplemented and unsupplemented groundwater entitlements will be converted to groundwater allocations based on the history of use of the existing entitlement. See Sections 3.2 and 3.6 for more information.

The new draft plan will also provide for the continued use of existing groundwater works in the currently non-declared areas of the Isaac–Connors and Don River subcatchments. A notification process for existing works will ensure that these works are authorised, licensed and accounted for in future water planning activities. See Section 3.6 for more details.

The new draft plan provides for greater specification of existing groundwater entitlements. All existing groundwater licences, except for those which are being converted to water allocations or have a purpose of mine de-watering, are to be amended as required to have a purpose, annual volumetric limit and conditions. Existing groundwater licences for stock purposes are no longer required.

### **3.2 Tradeable water allocations**

The National Water Initiative shows a clear preference for entitlements, wherever possible, to be held as tradeable water allocations. Tradeable water allocations promote efficiency and provide for movement of water to higher-value use by allowing the supply and demand forces that promote efficiency elsewhere in the economy to drive the water market.

Establishing tradeable water allocations separate from land provides security of tenure over the water entitlement. The specification of water allocation security objectives ensures appropriate security for water allocations and also provides a guide to their long-term performance.

Water allocation security objectives (WASOs) are defined for groups of water allocations in water resource plans in terms of one or more performance indicators which for supplemented water allocations in the new draft plan are expressed in terms of annual and/or monthly water sharing indices. For unsupplemented water allocations, the performance indicator is the annual volume probability which equates to the long-term probability of taking the total nominal volume for the water allocation group for a water year.

Performance indicators and WASOs for the new draft plan were developed using the new Integrated Quantity and Quality Model (hydrology model) for the Fitzroy Basin with a 108 year simulation period from 1900 to 2007. It is important to note

that these have been based on the simulated historic performance of the system and a range of assumptions, and do not provide a guarantee of future performance which will depend on climatic conditions and future rainfall.

### **3.2.1 Supplemented water allocations**

#### **3.2.1.1 Existing water allocations**

Existing supplemented water allocations will be transitioned without amendment to water allocations under the new plan. Furthermore they will continue to be managed under their respective resource operations licences and subject to the water sharing rules, water allocation change rules (trading rules), and seasonal assignment arrangements in the Fitzroy ROP.

#### **3.2.1.2 Callide Valley Water Supply Scheme**

Supplemented water allocations in the Callide Valley Water Supply Scheme will be established through the conversion of all existing interim water allocations (IWAs) for that scheme. The Callide Valley Water Supply Scheme consists of Callide Dam (136 300 ML) and Callide Weir (500 ML) on Callide Creek, and Kroombit Dam (14 600 ML) on Kroombit Creek.

This scheme is used to supply high priority water (4311 ML) directly from Callide Dam for urban and power generation purposes. The scheme also supplements groundwater supplies in a benefitted part of the Callide Valley alluviums through recharge releases from Callide and Kroombit Dams under raised dam levels. This currently supports medium priority allocations (19 527 ML) that access this groundwater resource for town, industrial and irrigation purposes. The scheme also supplies a small volume of risk priority water (443 ML) directly from recharge releases.

System performance has been under pressure over a long period both from over-allocation and overuse of the groundwater resource and more recently being subject to drought conditions. The issues and provisions relating to over-allocation of the groundwater resource are discussed further in Section 3.6.

The new draft plan proposes to establish tradeable water allocations for this scheme. Most elements for the water allocations (location, purpose and conditions) will be determined based on details that already exist on the entitlement.

However the over-allocation of the groundwater resource will be addressed by reducing the total volume for the allocations established from the existing medium priority IWAs from 19 527 ML to around 12 700 ML. This will be based on the history of use for each IWA over a specific ten-year period (1997–2007). Furthermore it is proposed to convert two medium priority IWAs that supply Banana Shire and Coreen Water Board to the high B priority group. This will enable these allocations to preferentially access available groundwater resources and so support town water supplies in the area.

The nominal volume and priority group will be based on the following:

- The nominal volume specified on a surface water allocation will be determined based on the volume stated on the surface water IWA.
- The nominal volume specified on the groundwater allocation will be determined based on the history of use of the groundwater IWA. See Section 3.6.6.2 for more information.
- There will be four priority groups for water allocations:
  - surface water IWAs which currently specify high priority will convert to high A priority group
  - surface water IWAs which currently specify risk priority will convert to risk priority group.
  - groundwater IWAs which currently specify medium priority will convert to medium priority group with the exception of two entitlements that supply water for Banana Shire and Coreen Water Board, which will convert to high B priority group.

The reduction in allocation from the supplemented groundwater resources and other arrangements will lead to improved performance of these allocations. Schedule 7 of the new draft plan sets out water allocation security objectives for the Callide Valley Water Supply Scheme. The minimum annual and monthly supplemented water sharing indices are shown in Table 1 (below).

Water sharing rules and water allocation change rules (trading rules) for the water allocations will be established in a future amendment to the Fitzroy ROP. It is expected that the water allocation change rules will include provision for the conversion of medium priority water allocations to high B priority allocations. This would allow for existing groundwater users to change to a more secure groundwater supply within the scheme. The particulars of such rules will need to consider local water availability and the recharge characteristics throughout the benefitted area. Preliminary assessments indicate that a conversion ratio of 3:1 may be appropriate for an allocation moving from the medium priority group to the high B priority group.

#### **3.2.1.3 Nogoia Mackenzie Water Supply Scheme**

More than 540 supplemented water allocations totalling 235 323 ML have been established for this scheme under the Fitzroy WRP 1999 and Fitzroy ROP. A recent amendment of the Fitzroy ROP also provided for more flexible water trading

rules by allowing for the conversion of medium priority allocations to additional high priority allocations. The new draft plan is consistent with the continuation of these and other arrangements in the existing Fitzroy ROP.

It is highlighted that the hydrologic assessments associated with the development of the new draft plan have resulted in an increased understanding of the historical streamflows and improved modelling and representation of all systems. Schedule 7 of the new draft plan sets out the water allocation security objectives for this scheme and the minimum annual and monthly supplemented water sharing indices are shown in Table 1.

The long-term performance for this scheme in particular has changed from earlier assessments underpinning the Fitzroy WRP 1999. Previous assessments showed a long-term monthly supplemented water sharing index of over 88 per cent for medium priority allocations. Updated assessments now show an index of 81 per cent for these allocations. Particular influences on this performance assessment include improved derivation of historical streamflows particularly during critical periods, modelling additional years prior to the start of the simulation period so as to have more realistic starting storage levels, and the extension of the simulation period up to 2007 which includes a recent significant dry period. The simulation period now goes from 1900 to 2007.

#### **3.2.1.4 Dawson Valley Water Supply Scheme**

More than 220 supplemented water allocations totalling 61 937 ML have been established for this scheme under the Fitzroy WRP 1999 and Fitzroy ROP. The new draft plan is consistent with the continuation of water sharing and other arrangements in the existing Fitzroy ROP. However the new draft plan also provides for the conversion of an existing medium priority IWA (105 ML) relating to the Back Creek Water Board to a tradeable water allocation. This can occur once the future arrangements of that water board are clarified.

Schedule 7 of the new draft plan sets out the water allocation security objectives for this scheme and the minimum annual and monthly supplemented water sharing indices are shown in Table 1.

In the advent of potential future projects in this area such as a raised Glebe Weir or Nathan Dam, the Fitzroy ROP would need to be amended to incorporate any changed operating, water sharing and allocation change rules. In the case where the Nathan Dam project proceeded, it would also likely lead to changes to the proposed unsupplemented water allocations in the Dawson River downstream of the dam. The nature of such changes would depend on the specific proposal by the proponent and the impacts on the performance of any established allocations.

#### **3.2.1.5 Lower Fitzroy and Fitzroy Barrage Water Supply Schemes**

More than 300 supplemented water allocations totalling 90 714 ML have been established for these schemes under the Fitzroy WRP 1999 and Fitzroy ROP. The new draft plan is consistent with the continuation of water sharing and other arrangements in the existing Fitzroy ROP.

Schedule 7 of the new draft plan sets out the water allocation security objectives for this scheme and the minimum annual and monthly supplemented water sharing indices are shown in Table 1.

The area is currently subject to investigations regarding the Lower Fitzroy Water Infrastructure Project. This project is about new water infrastructure developments on the Fitzroy River, such as a raised Eden Bann Weir or a new weir at Rookwood, to provide for greater security and additional water supplies to meet future regional water demands. The project is a joint partnership between SunWater and Gladstone Area Water Board with technical assistance from consultants GHD Pty Ltd. Rockhampton City Council is an important stakeholder in any proposal. The Lower Fitzroy River Infrastructure Project is part of the State Government's statewide Water Policy.

In the advent of future augmentation of either of these schemes, the Fitzroy ROP would need to be amended to incorporate any changed operating, water sharing and allocation change rules. In all cases the existing water allocations would be protected under these amendments.

Water supply security is a particular issue in this area with water supplies for both Rockhampton and the Stanwell power station dependent on these schemes. There has also been some consideration of a future change to the type of water sharing rules for these schemes, such as a move to capacity sharing. An amendment to the Fitzroy ROP would be required if this was to occur and full consultation with the water allocation holders and other stakeholders would be required. The new draft plan provides for the protection of the long-term performance of these water allocations and any such change would need to be consistent with both the plan's outcomes and water allocation security objectives.

**Table 1: WASOs for supplemented water allocations**

Water supply scheme	Priority group	Annual supplemented WSI minimum probability	Monthly supplemented WSI minimum probability
Callide Valley	High A (surface water)	95%	98%
	High B (groundwater)	95%	NA
	Risk (surface water)	60%	
	Medium (groundwater)	65%	
Nogoa-Mackenzie	High	95%	98%
	Medium	NA	81%
Dawson Valley	High	95%	98%
	Medium and medium A	NA	82%
Lower Fitzroy and Fitzroy Barrage	High	95%	98%
	Medium	NA	82%

### 3.2.2 Unsupplemented water allocations

#### 3.2.2.1 Existing water allocations

Under the Fitzroy WRP 1999 and Fitzroy ROP, 175 unsupplemented water entitlements (mostly to take water under conditions commonly known as water harvesting) were converted to unsupplemented water allocations along the Nogoa, Mackenzie and Fitzroy Rivers.

These existing unsupplemented water allocations will be transitioned as water allocations under the new plan. Furthermore they will continue to be subject to the water sharing rules, water allocation change rules (trading rules), and seasonal assignment arrangements in the Fitzroy ROP.

The new draft plan also proposes to amend the existing unsupplemented water allocations so that all unsupplemented water allocations have the same elements. It is proposed that all existing unsupplemented allocations would state a daily volumetric limit (ML) that would be consistent with the maximum rate, expressed in litres per second, currently stated on each allocation. The maximum rate would also be amended to increase by a factor of 1.3 to reflect the larger instantaneous capacity of most pump installations. The ongoing management of these allocations, including access and sharing would essentially remain unchanged as the current rate specified on the allocation reflected the operational duty points of the original works.

#### 3.2.2.2 Additional water allocations to take unsupplemented surface water

The new draft plan proposes to establish additional unsupplemented water allocations to take surface water through the conversion of existing licences to take unsupplemented water in the following watercourses:

- Nogoa River from the upstream limit of Fairbairn Dam at AMTD 737.5 km to its junction with Theresa Creek
- Theresa Creek from its junction with Retreat Creek at AMTD 15.0 km to its junction with the Nogoa River
- Retreat Creek, including anabranches, from its junction with Kettle Creek at AMTD 23.6 km to its junction with Theresa Creek
- Comet River, including anabranches, from Lake Brown gauging station AMTD 199.2 km to its junction with the Nogoa River
- Dawson River from Utopia Downs Gauging Station at AMTD 453.5 km to its junction with the Mackenzie River, including sections of tributaries where Dawson River flows are accessible.

### 3.2.2.3 Elements of new water allocations

Chapter 5 Part 2 Division 7 (Section 87–99) of the new draft plan proposes how unsupplemented surface water allocations would be specified and determined. Water allocations would have elements of purpose, maximum rate, daily volumetric limit and annual volumetric limit.

The *daily volumetric limit*, expressed in megalitres (Section 95 of the new draft plan) would generally be based on the rate that may be stated on the existing licence, or for authorisations which do not have a stated rate, a volume linked to any associated pump size. Table 2 shows the daily volumetric limit (ML) for allocations based on an associated pump size. The values in the table reflect the capacity of a pump to take water over the course of a day under normal operating conditions.

The *maximum rate*, expressed in litres per second (Section 94 of the new draft plan) would generally be based on the capacity of any pump associated with the authorisation. Table 2 shows the maximum rate (litres/sec) for authorisations linked to any associated pump size. The values in the table reflect the maximum capability of pumps to take water.

**Table 2: Maximum rates and daily volumetric limits for various pump sizes**

Pump size (mm)	Maximum rate (litres/sec)	Daily volumetric limit (ML/day)
32	11	0.6
40	15	1
50	35	1.5
65	60	2.6
80	80	3.9
100	110	5.6
125	140	7.8
150	165	9.9
200	215	16
250	275	21.6
300	340	25.9
350	415	30.2
400	500	37.2
500	780	56.2
600 to 660	1400	95
750	2375	160
800	2900	201

The annual volumetric limit, expressed in megalitres (Section 96 of the new draft plan) would generally be determined by multiplying the daily volumetric limit by a prescribed number of days. The number of days would depend on the location and flow condition of the existing licence. Table 3 shows the number of days to be used depending on the location and flow conditions of the existing licence.

However the annual volumetric limit for allocations converted from licences that state an annual volume, would be the stated volume. For those allocations converted from licences that state an area that may be irrigated, the annual volumetric limit would be the area in hectares multiplied by six.

Future management of unsupplemented water allocations would be based on the daily volumetric limit and annual volumetric limit while the maximum rate would be used to assess any applications for a development permit.

Unsupplemented water allocations would also include the elements of nominal volume and water allocation group. The nominal volume would reflect a water allocation's share of the resource and become a form of currency in any potential trading of the water allocation. The nominal volume for each water allocation will be established through an amendment to the Fitzroy ROP and would reflect the long-term average take for the water allocation. Each unsupplemented water allocation would also belong to a water allocation group for which the plan specifies water allocation security objectives. Table 3 also shows the water allocation groups for the new unsupplemented water allocations to take surface water.

**Table 3: Water allocation groups to take unsupplemented surface water**

Place	Access condition	Water allocation group	Number of days
Nogoa River from the upstream limit of Fairbairn Dam at AMTD 737.5km to its junction with Theresa Creek	2592 ML/day	Class 0A	NA
Theresa Creek from its junction with Retreat Creek at AMTD 15.0 km to its junction with the Nogoa River	more than 0 ML/day	Class 8A	24 days
Retreat Creek, including anabranches <sup>1</sup> , from its junction with Kettle Creek at AMTD 23.6km to its junction with Theresa Creek			
Comet River, including anabranches <sup>2</sup> , from Lake Brown gauging station AMTD 199.2km to its junction with the Nogoa River	less than 864 ML/day	Class 9A	24 days
	equal to or more than 864 ML/day	Class 9B	20 days
Dawson River from its junction with Mimosa Creek at AMTD 133km to its junction with the Mackenzie River, including sections of tributaries where Dawson River flows are accessible <sup>3</sup>	1296 ML/day	Class 10A	20 days
	2592 ML/day	Class 10B	19 days
Dawson River from the end of the supplemented section at AMTD 18.37km to its junction with the Mackenzie River, including sections of tributaries where Dawson River flows are accessible <sup>3</sup>	0 to 25 ML/day	Class 10C	NA
Dawson River from Orange Creek Weir at AMTD 270.7km to its junction with Mimosa Creek at AMTD 133km, including sections of tributaries where Dawson River flows are accessible <sup>3</sup>	1296 ML/day	Class 11A	20 days
	2592 ML/day	Class 11B	19 days
Dawson River from the upstream limit of Glebe Weir at AMTD 356.5km to Orange Creek Weir at AMTD 270.7km, including sections of tributaries where Dawson River flows are accessible <sup>3</sup>	1296 ML/day	Class 12A	20 days

Dawson River from Utopia Downs Gauging Station at AMTD 453.5km to the upstream limit of Glebe Weir at AMTD 356.5km, including sections of tributaries where Dawson River flows are accessible <sup>3</sup>	up to 1296 ML/day	Class 13A	20 days
	up to 25 ML/day	Class 13C	NA

Notes:

1 An access condition on a water licence in an anabranch will be translated to an equivalent access condition for Retreat Creek.

2 An access condition on a water licence in an anabranch will be translated to an equivalent access condition for Comet Creek.

3 An access condition on a water licence in an anabranch will be translated to an equivalent access condition for Dawson River.

### 3.2.2.4 Defining water allocation security

Unsupplemented water allocations feature a higher level of specification than water licences. These allocations have the added requirement that all decisions associated with changing them, for example through trading, must be consistent with their associated water allocation security objectives. Many decisions, including the volumes, location and flow conditions of new and existing water entitlements, can influence the long-term performance of unsupplemented water allocations.

The performance indicator for existing and new unsupplemented surface water and groundwater allocations in the new draft plan is the annual volume probability which equates to the long-term probability of taking the total nominal volume for the water allocation group for a water year. The minimum annual volume probabilities for both existing and new unsupplemented surface water allocations are shown in Table 4.

This indicator is a change from those in the Fitzroy WRP 1999 which relate to the 30 per cent, 50 per cent and 75 per cent performance profile for each water allocation group. It is considered that this indicator will provide for a more consistent and practical approach to future water trading rules. The profile of performance will still be a major consideration in the development of any future water sharing and allocation change rules (Sections 28 and 29 of the new draft plan).

**Table 4: Minimum annual volume probabilities for unsupplemented surface water allocations**

Place	Flow condition	Water allocation group	Annual volume probability
Nogoa River from the upstream limit of Fairbairn Dam at AMTD 737.5 km to its junction with Theresa Creek	2592 ML/day	Class 0A	17%
Mackenzie River from the Isaac Mackenzie water harvesting upstream limit to the Dawson River junction	2592 ML/day	Class 1A	73%
	4320 ML/day	Class 1B	71%
Nogoa and Mackenzie rivers from the Comet Mackenzie waterharvesting upstream limit to the Isaac Mackenzie waterharvesting upstream limit	2592 ML/day	Class 2A	47%
	4320 ML/day	Class 2B	47%
Nogoa River from the Theresa Creek junction to the Mackenzie waterharvesting upstream limit	2592 ML/day	Class 3A	38%
Mackenzie River from the Springton Creek junction to the Dawson River junction	No flow condition and 9 ML/day	Class 4C	95%
Fitzroy River from the Dawson River junction to the Fitzroy Barrage	2592 ML/day	Class 5A	61%
	4320 ML/day	Class 5B	73%

Fitzroy River from the Dawson River junction to upstream limit of Eden Bann Weir	No flow and 9 ML/day	Class 6C	95%
	260 ML/day	Class 7D	93%
Theresa Creek from its junction with Retreat Creek at AMTD 15.0km to its junction with the Nogoia River; and Retreat Creek, including anabranches <sup>1</sup> , from its junction with Kettle Creek at AMTD 23.6km to its junction with Theresa Creek	More than 0 ML/day	Class 8A	48%
Comet River, including anabranches <sup>2</sup> , from Lake Brown gauging station AMTD 199.2km to its junction with the Nogoia River	Less than 864 ML/day	Class 9A	55%
	Equal or more than 864 ML/day	Class 9B	47%
Dawson River from its junction with Mimosa Creek at AMTD 133 km to its junction with the Mackenzie River, including sections of tributaries where Dawson River flows are accessible <sup>3</sup>	1296 ML/day	Class 10A	68%
	2592 ML/day	Class 10B	68%
Dawson River from the end of the supplemented section at AMTD 18.37 km to its junction with the Mackenzie River, including sections of tributaries where Dawson River flows are accessible <sup>3</sup>	0 to 25 ML/day	Class 10C	66%
Dawson River from Orange Creek Weir at AMTD 270.7 km to its junction with Mimosa Creek at AMTD 133 km, including sections of tributaries where Dawson River flows are accessible <sup>3</sup>	1296 ML/day	Class 11A	63%
	2592 ML/day	Class 11B	60%
Dawson River from the upstream limit of Glebe Weir at AMTD 356.5 km to Orange Creek Weir at AMTD 270.7 km, including sections of tributaries where Dawson River flows are accessible <sup>3</sup>	1296 ML/day	Class 12A	63%
Dawson River from Utopia Downs Gauging Station at AMTD 453.5 km to the upstream limit of Glebe Weir at AMTD 356.5 km, including sections of tributaries where Dawson River flows are accessible <sup>3</sup>	up to 1296 ML/day	Class 13A	60%
	up to 25 ML/day	Class 13C	67%

Notes:

- 1 An access condition on a water licence in an anabranch will be translated to an equivalent access condition for Retreat Creek.
- 2 An access condition on a water licence in an anabranch will be translated to an equivalent access condition for Comet Creek.
- 3 An access condition on a water licence in an anabranch will be translated to an equivalent access condition for Dawson River.

### 3.3 Meeting future water needs

Existing and future water needs will be met through the use of existing entitlements, including the opportunity to acquire access from both supplemented and unsupplemented water allocations as established. Water markets are now established in many parts of the Fitzroy Basin and the new draft plan will provide for additional water allocations as discussed in previous sections.

The new draft plan also provides for additional reserves of unallocated water for both surface water and groundwater in specific parts of the plan area. The Fitzroy WRP 1999 accommodated additional unallocated surface water including a specific reserve for Nathan Dam on the Dawson River.

A moratorium (Appendix B) released in December 2010 prevents pre-emptive development proposals that would be contrary to the new draft plan provisions and replaces two existing groundwater moratoriums. The moratorium applies to:

- the construction of new works for taking groundwater from those parts of the Don River subcatchment and Isaac–Connors Rivers subcatchment in which groundwater has not been previously managed
- applications for water licences to take groundwater in the existing Callide, Fitzroy, Highlands and Great Artesian Basin subartesian declared areas in the Fitzroy Basin
- applications for water licences to take surface water from the Downstream of the Fitzroy Barrage subcatchment area
- applications for water licences to interfere with the flow of water by impoundments (such as dams and weirs) on watercourses throughout the Fitzroy Basin.

The moratorium will be in existence until finalisation of the new plan. Section 3.3.2 provides information on how particular applications—received prior to the commencement of the new plan—to take groundwater, surface water from a watercourse in the subcatchment Downstream of the Fitzroy Barrage and to interfere with the flow of water by impoundment would be dealt with.

#### 3.3.1 Additional unallocated water

The Fitzroy WRP 1999 identified small reserves of supplemented water that had not been allocated at the time as well as unallocated water reserves providing for additional development including water reserved for the proposed Nathan Dam project (up to 190 000 ML/a). This project has been delayed and the reserve has not yet been allocated.

The Fitzroy ROP also provided a process for the release of unallocated water and specifies total volumes similar to those indicated in the overview report to the Fitzroy WRP 1999. Those volumes of unallocated water include:

- up to 300 000 ML/a of mean annual diversion in the Isaac–Connors, Lower Mackenzie and Fitzroy River catchments
- up to 40 000 ML/a of mean annual diversion in the Comet, Nogoia and Upper Mackenzie system upstream of Bingegang Weir
- up to 11 500 ML/a of mean annual diversion from the Dawson River upstream of Taroom.

It is highlighted that the Fitzroy ROP indicates that the 40 000 ML/a reserve upstream of Bingegang Weir is no longer available because of significant development of overland flow works prior to the commencement of the WRP amendment process in late 2001.

The Fitzroy ROP provides for a number of releases of unallocated water from this reserve, but as yet no releases have occurred.

The development of a new draft plan provides an opportunity to review and respecify these reserves and take into account existing water users, environmental flow objectives and requirements, future water demands including new water infrastructure and climate change. Reserves of unallocated water to provide for town water supplies, industry, Indigenous purposes and general purposes are to be specified in the new draft plan. The new draft plan includes reserves for both surface water and groundwater in particular parts of the plan area. The reserves proposed are similar to the existing Fitzroy WRP 1999 but have been reconfigured to provide specifically for:

- new water infrastructure projects identified in the Central Queensland Regional Water Supply Strategy and government program of works (Connors River Dam, Nathan Dam and Lower Fitzroy weirs)
- reserves throughout the basin for state purposes (projects of state and regional significance, town water supply and community use)
- reserves for Indigenous purposes
- reserves for general purposes.

The new draft plan provides for unallocated water reserves totalling 301 900 ML (surface water) and 16 200 ML (groundwater), and will support future growth and water supply security across the plan area.

The provisions relating to unallocated water are contained in Chapter 5, Part 1, Division 3 and Schedule 8 of the new draft plan.

As part of the reserves for surface water, the new draft plan specifies an unallocated water reserve in the area downstream of the Fitzroy Barrage. Future development in this area will be limited to a strategic reserve of 1000 ML for state purposes.

Furthermore there will also be an unallocated groundwater reserve of 20 000 ML from naturally very saline water in the coastal parts of the Fitzroy GMA. This is to provide for possible expansion of the salt production industry.

Importantly, the new draft plan provides reserves of unallocated water for specific water infrastructure projects in the plan area. These include Connors River Dam, Nathan Dam on the Dawson River and Lower Fitzroy storages. These are discussed further in Section 3.3.1.1.

Surface water reserves are specified by subcatchment areas which are shown in a map in Schedule 2 of the new draft plan. Groundwater reserves are specified by groundwater management areas or groundwater sub-areas which are shown in maps in schedules 3 and 4 of the new draft plan.

The reserves will be available for a range of purposes and in forms such as water allocations and water licences. They are specified in terms of nominal volume, annual volumetric limit or mean annual diversion with the exact form of any entitlement to be subject to the release process to be specified in an amended Fitzroy ROP.

The following sections outline the range of reserves provided for in the new draft plan.

### **3.3.1.1 Strategic reserves for water infrastructure**

The government has demonstrated its support for the Central Queensland Regional Water Supply Strategy that includes provision for new water infrastructure proposals in the Fitzroy Basin when future water supplies are needed and viable business cases are presented. The Fitzroy WRP 1999 provided explicitly for Nathan Dam (up to 190 000 ML/a) on the Dawson River and also accommodated additional volumes of unallocated water at other locations in the plan area. The new draft plan proposes strategic reserves specifically for three water infrastructure projects in the Fitzroy Basin.

#### **Connors River Dam**

A business case for the Connors River Dam Project (373 000 ML capacity) near Nebo is currently being developed by SunWater primarily to meet the water supply needs of new mining developments in the Bowen and Galilee Basins. The project has been declared a significant project under the *State Development and Public Works Organisation Act 1971* and a draft environmental impact statement (EIS) was released in February 2010 for public comment. A supplementary report to the draft EIS has now been received by the Coordinator General for further consideration. It is anticipated that the EIS will be finalised early next year with construction of the dam beginning later next year.

- The new draft plan provides a strategic reserve of up to 56 400 ML nominal volume which is consistent with the draft EIS.

#### **Nathan Dam on Dawson River**

A business case for Nathan Dam (880 000 ML to 1 100 000 ML capacity) on the Dawson River near Taroom is currently being developed by SunWater to meet the water supply needs of new mining developments. The case for Nathan Dam has changed from a focus primarily on irrigated agriculture (10 years ago) to a current focus on providing high-security water supplies for new mines and regional towns. The EIS for the Nathan Dam project is expected towards the end of 2010. This project has been declared a significant project under the *State Development and Public Works Organisation Act 1971*.

- The new draft plan provides a strategic reserve of up to 90 000 ML nominal volume which would provide for the Nathan Dam option under consideration by SunWater.

If a project other than Nathan Dam was considered in the Dawson River e.g. raised Glebe Weir, this reserve could also be used to support such water infrastructure.

#### **Lower Fitzroy storages**

Investigations for new or raised weirs on the Fitzroy River upstream of Rockhampton are currently being undertaken jointly by SunWater and the Gladstone Area Water Board. Rockhampton Regional Council, while not involved in the joint venture, is also an integral stakeholder in any proposal. The case for new or raised weirs depends on additional water demands near Gladstone and/or increased water supply security for Rockhampton. The Lower Fitzroy River Infrastructure Project is part of the State Government's statewide water policy.

- The new draft plan provides a strategic reserve of up to 76 000 ML nominal volume which is consistent with the

## Central Queensland Regional Water Supply Strategy.

Any water granted from the strategic water infrastructure reserves for water infrastructure projects are expected to be granted as water allocations.

### **3.3.1.2 Other unallocated surface water reserves**

Figure 3 shows the unallocated surface water reserves including those for future water infrastructure.

The strategic reserves, 1000 ML for Downstream of the Fitzroy Barrage subcatchment area and 15 000 ML elsewhere in the plan area, will be available for a state purpose which includes water for projects of state significance, projects of regional significance, town water supply and community use. Water granted from the strategic reserve for state significant and regional significant projects will be issued as a water licence for the life of the project and returned to the strategic reserve on conclusion of the project.

The strategic reserve of 5000 ML will be available for projects that help Indigenous communities achieve their economic and social aspirations. Water granted for Indigenous purposes will be issued as a water licence for the life of the project and returned to the strategic reserve on conclusion of the project

The general reserves totalling 58 500 ML will be available in particular subcatchments and for any purposes.

### **3.3.1.3 Unallocated groundwater reserves**

Figure 4 shows the unallocated groundwater reserves.

The strategic reserves, totalling 4950 ML, will be available for a state purpose which includes water for projects of state significance, projects of regional significance, town water supply and community use.

The general reserves, totalling 31 250 ML, will be available in particular groundwater management areas, groundwater sub-areas or groundwater units for any purposes. It is highlighted that part of the general reserve is a 20 000 ML volume from Fitzroy Groundwater Unit 1 which contains naturally very saline water in the coastal parts of the Fitzroy groundwater management area.

### **3.3.1.4 Process for releasing unallocated water**

Water use efficiency is now a national priority as Australians increasingly come to grips with the reality of living on the driest inhabited continent. While the new draft plan provisions are intended to promote progressive efficiency for existing uses, those uses associated with the release of any unallocated water will also need to satisfy efficiency and other criteria to ensure consistency with overall planning goals.

The new draft plan contains a provision to replace the unallocated water process stated in Chapter 6 of the current Fitzroy ROP. A new process for releasing unallocated water will be included in the Fitzroy ROP when it is amended to implement the new plan. Releases are likely to occur in stages as industries and water demands materialise.

Sustainability goals and best practice will guide the release of unallocated water to promote efficiency, economic viability and to protect the ecological outcomes in the new draft plan.

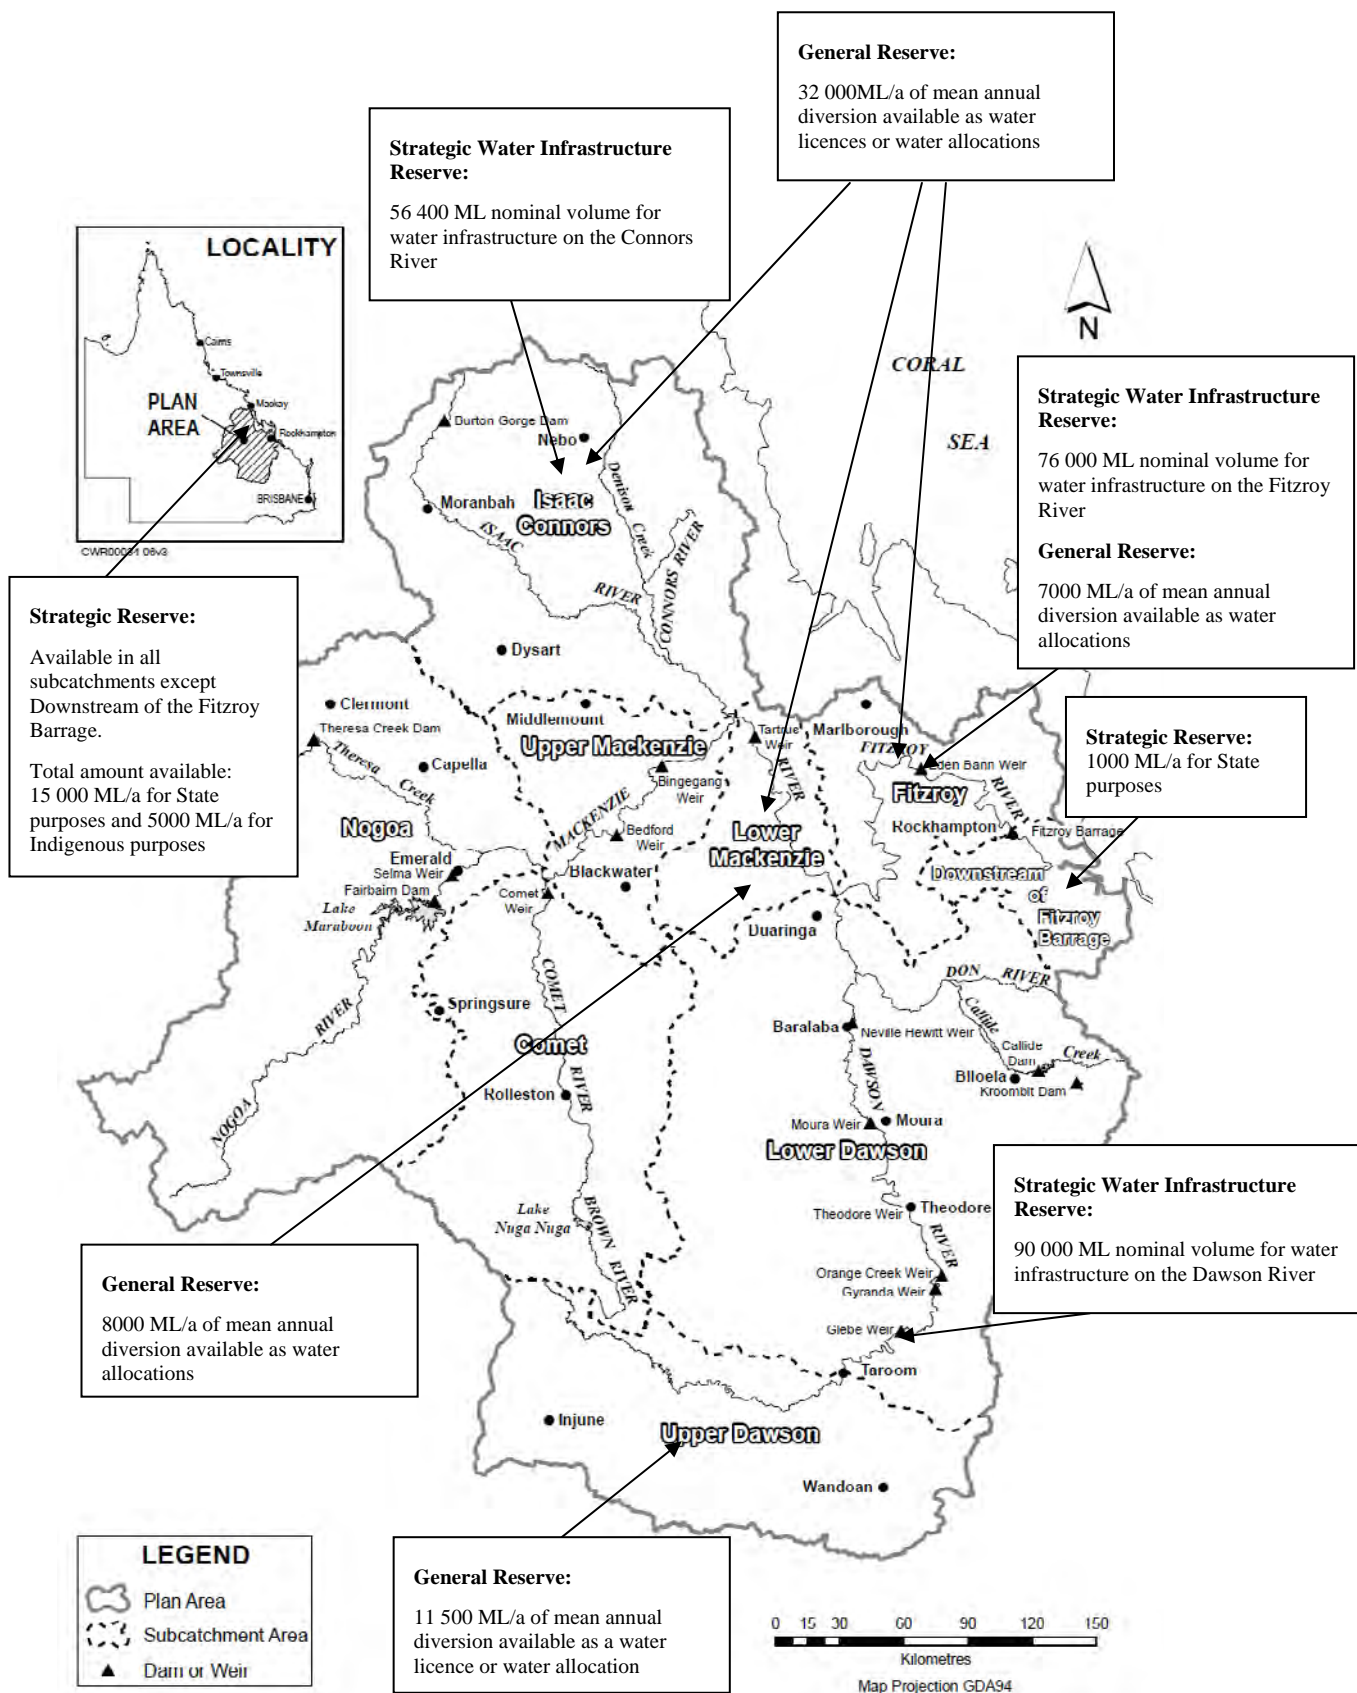

These goals will be supported by measures that include:

- Alternative water sources: In deciding whether to make additional water available, the department will consider whether the proposed requirements can be met from alternative sources (for example, from existing unused entitlements or through gains made by improving water use efficiency). This will ensure that the community derives the maximum benefit from its water resources.
- Generally water will be made available under a market-based competitive model such as tender or auction. Prices are likely to be influenced by demand, especially where there is competing interest for high-value uses. A reserve price will generally be set for the unallocated water.

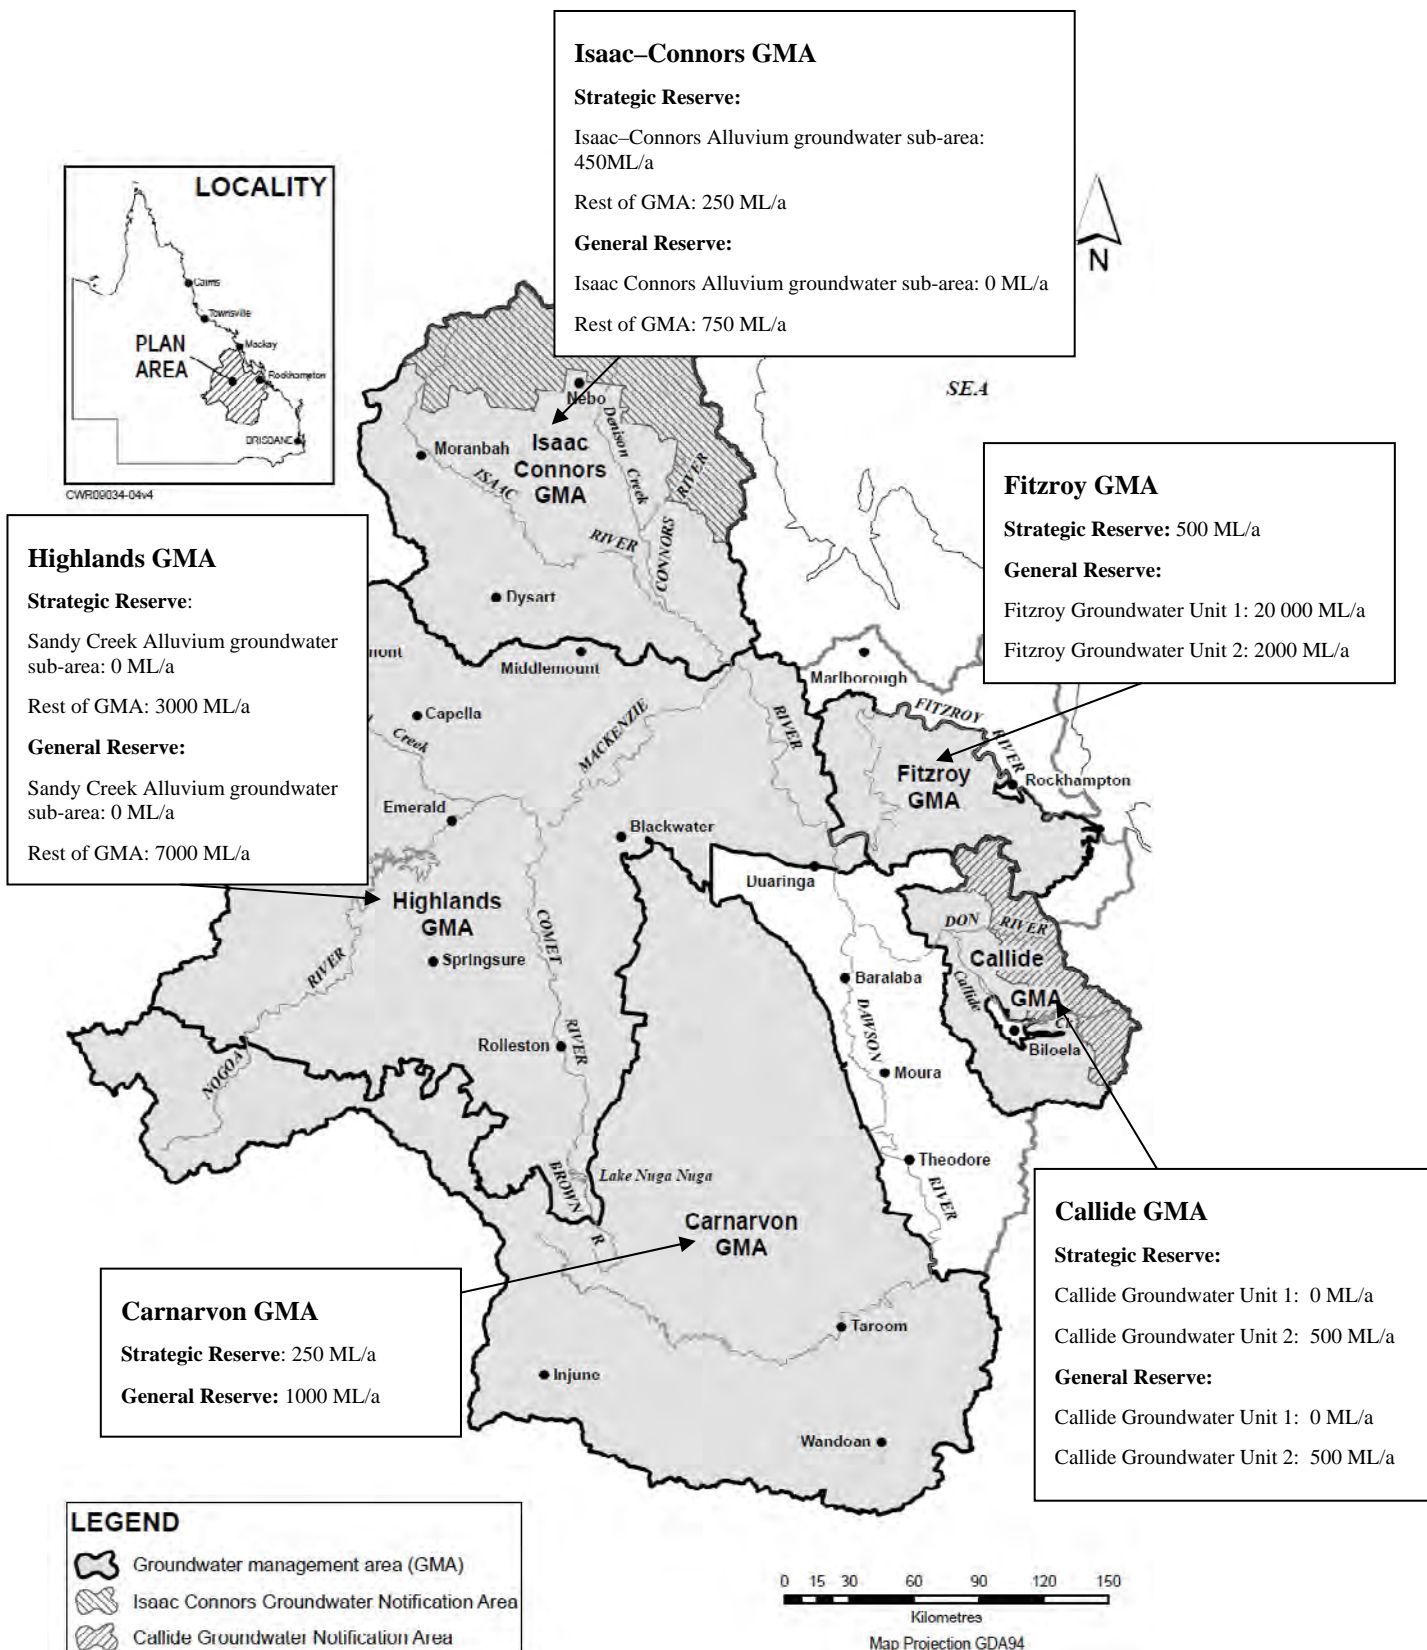

### **3.3.1.5 Interim arrangements for applications about unallocated water**

Section 36 of the new draft plan provides interim arrangements that allow for particular applications to take water (under Section 206 of the Water Act) for State purposes and stock and domestic purposes to be dealt with prior to the finalisation of the new plan and the amendment of the Fitzroy ROP.

**Figure 3: Unallocated surface water reserves**

**Figure 4: Unallocated groundwater reserves**

CAS1752-3

### **3.3.2 Particular applications made before the Fitzroy ROP is amended**

Chapter 5 Part 1 Division 2 of the new draft plan directs that particular applications received prior to the plan's commencement would be refused. This includes applications to take groundwater, surface water from a watercourse in the subcatchment Downstream of the Fitzroy Barrage and to interfere with the flow of water by impoundment. Exemptions include applications for town water supplies and those for projects of state and regional significance.

Furthermore, applications that would increase the amount of water that may be taken will be refused prior to an amendment to the Fitzroy ROP to state a new process for dealing with unallocated water (Section 35 of the new draft plan). Exemptions include applications for a State purpose and an Indigenous purpose.

Stakeholders will have the opportunity to obtain unallocated water through the process for the release of unallocated water that will be provided in the amended Fitzroy ROP.

### **3.3.3 Granting and amending interim resource operations licences**

The new draft plan contains provisions for granting and amending interim resource operations licences (iROL) to provide for the necessary authorisation to interfere with the flow of water before construction or augmentation of any water infrastructure. These provisions would allow for the construction of new water infrastructure located outside an existing water supply scheme (such as Connors River Dam) in the event that the new water infrastructure commenced prior to the finalisation of an amendment to the Fitzroy ROP.

The construction of new water infrastructure located within an existing water supply scheme (such as the proposed raising of Glebe Weir), can occur through an amendment to an existing resource operations licence under the Act (Section 113(1)(c) or 111A) either with ROL holder consent or under a process in the resource operations plan. The latter would require an amendment of the Fitzroy ROP to include a process for amending a ROL. Prior to the new infrastructure reaching the operational stage the Fitzroy ROP would be amended to include the operational rules for the infrastructure.

### **3.3.4 Interference with the flow of water**

Chapter 5 Part 2 Division 4 of the new draft plan proposes additional criteria when dealing with any licence applications to interfere with the flow of water by impoundment, where the purpose of interference is:

- to store water for stock or domestic purposes
- to pool water behind the structure to enable an authorised pump to function properly
- to store water for town water supply purposes
- to satisfy the requirements of an environmental authority issued under the *Environmental Protection Act 1997*
- related to a proposed water entitlement to take water granted from unallocated water under a release process.

Additional criteria against which applications would be assessed are stated. These criteria relate to the potential impacts of the proposed interference on the environment and on cultural values. Limits for the size of particular impoundments also apply.

For example, if the structure is designed to pool water to allow a pump to function properly to divert water under an existing entitlement, the proposed storage capacity cannot exceed five megalitres. Additionally existing water supplies on the property and availability of water at the proposed site would be considerations with regard to applications to store water for stock or domestic purposes.

## **3.4 Better defined entitlements**

Clearly defined entitlements are important for sustainably allocating and managing water resources, and provide water users with greater confidence in planning than they might previously have enjoyed.

Many unsupplemented water entitlements to take either water from a watercourse or groundwater do not include a volumetric limit. Licences for the purpose of irrigation are often specified in terms of an area that can be irrigated and the absence of a volumetric limit can lead to increasing and sometimes inequitable take of water.

### **3.4.1 Watercourse licences**

Chapter 5 Part 2 Division 8 of the new draft plan proposes that existing and new unsupplemented surface water licences are to include the following licence terms:

- the purpose for which the water is to be used
- the maximum rate for taking water, expressed in litres per second
- the daily volumetric limit that may be taken

- the nominal entitlement or maximum volume that may be taken in a year
- conditions, including any flow conditions, or conditions for storing the water
- the monthly volumetric limit, if applicable.

The purpose stated on an unsupplemented surface water licence will be either agriculture or any. Agriculture includes normal uses associated with primary production e.g. stock-watering, irrigation, agriculture and aquaculture. Any also includes urban, mining and industrial uses i.e. water can be used for any purpose including rural purposes such as feedlots and piggeries.

The maximum rate, daily volumetric limit and nominal entitlement would be determined in a similar manner to that described for unsupplemented water allocations in Section 3.2.2.3 of this report. For licences that state an area that may be irrigated, a monthly volumetric limit equating to two ML for each hectare will also be added to the licence.

It is proposed that water entitlements would be amended to include these elements over a period of time in response to other more general licence amendments.

### **3.4.2 Overland flow water licences**

Section 112 of the new draft plan requires that all new overland flow water licences will state:

- the purpose for which the water is to be used i.e. either agriculture or any
- at least one of the following:
  - the maximum rate at which water can be taken
  - the daily volumetric limit that may be taken
  - the nominal entitlement
  - the maximum volume of water that may be stored under the licence
  - conditions, if any.

### **3.4.3 Groundwater licences**

Chapter 5 Part 3 Division 2 of the new draft plan requires that all existing and new groundwater licences are to state particular licence terms, including:

- the purpose for which the water is to be used will be either agriculture or any
- nominal entitlement—if this is already specified on the existing licence, then that volume, otherwise a volume determined by the chief executive
- conditions, if any.

## **3.5 Regulation of overland flow water**

The Fitzroy WRP 1999 was amended in 2005 to provide for regulation of overland flow water. The amendment followed hydrological investigations which concluded that the Fitzroy WRP 1999 outcomes would be at risk if uncontrolled overland flow development were allowed to continue. The new draft plan proposes to build on the strategies in the Fitzroy WRP 1999.

### **3.5.1 Authorisation of existing and new take of overland flow water**

Under the new draft plan existing and new overland flow take will continue to be authorised for stock and domestic use, to meet the requirements of an environmental authority or a development permit for an environmentally relevant activity, and to capture contaminated run-off.

The Fitzroy WRP 1999 allows for the take of overland flow water by small scale storages with a capacity of up to 5 ML. Under the new draft plan it is proposed to increase the authorised capacity to 50 ML. Storages up to 50 ML for purposes other than ponded pasture and water spreading will be able to be constructed without the need to purchase unallocated water. The exemption for ponded pasture and water spreading is necessary to prevent take of large volumes of water by incremental construction of multiple low cost small scale storages. Examples of projects that small-scale storages may provide for include agriculture, small community purposes, works for managing urban stormwater and groundwater recharge works. This change will provide for less regulatory impact on the rural sector without compromising plan outcomes.

It is also proposed to authorise any incidental take of overland flow water associated with the storage of coal seam gas water that is to be used for a beneficial use (see Section 3.5.6 for further information).

New overland flow works which are authorised under the new plan will be either self assessable or assessable development under the *Sustainable Planning Act 2009*. Those that are classified as assessable include works for capturing contaminated run-off and works for storing coal seam gas water that also incidentally take overland flow water. Those works that are classified as self assessable include works for stock and domestic purposes, works up to 50 ML capacity and works for the purposes of complying with an environmental authority or a development permit for an environmentally relevant activity. For information about the assessable and self assessable development codes that apply to new overland flow development go to <[http://www.derm.qld.gov.au/water/management/overland\\_flow/index.html](http://www.derm.qld.gov.au/water/management/overland_flow/index.html)>

Any proposal for new overland flow works not otherwise authorised under the new draft plan is assessable development and will require both:

- a licence to take water, subject to the availability and release of unallocated water (see Section 3.3.1.4)
- a development permit issued under the *Sustainable Planning Act 2009*.

### **3.5.2 Notification process for existing OLF storages**

Take of overland flow water by existing works (built before September 2001) will continue to be authorised under the new draft plan and any works that have not been notified under the Fitzroy WRP 1999 will still require notification.

Notification is now required for existing overland flow works associated with mines (built before the commencement of the new plan) if the works are not otherwise authorised under the new plan. Mines must notify the chief executive of the existing works within 12 months of the commencement of the new plan.

Notification of existing overland flow storages will provide essential data to enable the department to more effectively monitor and evaluate the level of overland flow development in the basin.

### **3.5.5 New take of overland flow water for mining purposes**

Under the Fitzroy WRP 1999, new take of overland flow water for the purpose of mining is authorised until the Fitzroy ROP is amended to include overland flow water. The new draft plan proposes to replace this provision with a requirement to purchase unallocated water for new works not authorised under the new plan. The new draft plan provides for interim arrangements that will allow for the purchase of unallocated water between the final plan and the final amended Fitzroy ROP, but only for those mining projects considered to be of state or regional significance.

Furthermore the existing provision to authorise any take of overland flow water of not more than the amount necessary to divert water around a mine site is proposed to be removed. Any new take of overland flow water for this purpose will now generally require the acquisition of a water entitlement.

The existing approach in the Fitzroy is considered inequitable in how it deals with different water using sectors and these changes will lead to a more consistent approach.

### **3.5.6 Incidental take of overland flow water associated with coal seam gas water**

The take of coal seam gas water is dealt with under the *Petroleum Act 1923* and the regulation of its disposal is dealt with under the *Environmental Protection Act 1997*. The new draft plan proposes to authorise the incidental take of overland flow water associated with the storage of coal seam gas water in circumstances where the water cannot be stored for beneficial reuse, other than in an overland flow storage. The works for taking the water will be assessable development under the *Sustainable Planning Act 2009* and will require a development permit. The take of overland flow water will only be authorised while it is associated with the storage of coal seam gas water. This new proposed provision seeks to support the beneficial use of coal seam gas water.

### **3.5.7 Continuation of the effect's of the overland flow moratorium in part**

The Fitzroy WRP 1999 continues the effects of the overland flow moratorium. This effectively prevents landholders, with existing storages that store both water taken from a watercourse and overland flow water, from reconfiguring existing storages or building new storages to store water taken from a watercourse (water harvesting). This provision aims to limit any increased take of overland flow water. The new plan proposes that the continued effect of the moratorium will only apply to sections of the Comet River and Theresa Creek areas where plan outcomes are considered to be at most risk from any increased take of overland flow water. This provision will remain in effect until the Fitzroy ROP is amended to include the management of overland flow water and it is expected that un-supplemented water allocations to take water from watercourses would also be established at that time.

## 3.6 Regulation of groundwater

The new draft plan provides a framework for adaptive management of all subartesian groundwater in the plan area. It allows for management of subartesian water resources at an appropriate scale in response to an assessment of risk that includes consideration of the level of allocation compared with recharge and vulnerability to threats and concerns such as salinity, rising water tables, threats to groundwater dependent ecosystems and surface water–groundwater connectivity, local pumping effects, development pressures and community conflicts.

The new draft plan provides a consistent approach to the taking of groundwater for stock or domestic purposes across the plan area in that no licence will be required. Bore logs will still need to be submitted as a mandatory requirement of groundwater well drillers.

The new draft plan provides for future development through the specification of unallocated water reserves for each of the five groundwater management areas (GMAs). This effectively provides a cap on total groundwater extractions throughout the plan area. See Section 3.3. However, extractions for de-watering while still requiring licensing and applications will be decided under the provisions of the *Water Act 2000*.

The new draft plan provides for the amendment of all existing licences to take groundwater to include a purpose, nominal entitlement and conditions, if required.

It has been determined that the level of development and use of subartesian water in some parts of the plan area where licences have not been required in the past poses little risk to the water resource. The areas are the central and lower Dawson, lower Fitzroy north of the river and south-east extremity of the Fitzroy below the Fitzroy Barrage. Those areas are unshaded on the map provided in Schedule 3 of the new draft plan. Management in those areas will continue to involve some monitoring of water levels and assessment of activity by evaluation of bore logs submitted as a mandatory requirement of groundwater well drillers.

The Callide Valley Water Supply Scheme area (centred on Biloela) is not part of the Callide groundwater management area and also remains unshaded on the map provided in Schedule 3 of the new draft plan. Water allocations to take supplemented groundwater will be established through the conversion of existing medium priority interim water allocations in that area and will be managed under a resource operations licence for the Callide Valley Water Supply Scheme. See Section 3.2.1.2.

In the remainder of the plan area, specific management provisions are provided in the new draft plan to allow appropriate management of subartesian groundwater in five Groundwater Management Areas (GMAs). Schedule 3 of the new draft plan outlines these GMAs which are named as follows:

- Callide GMA
- Isaac–Connors GMA
- Highlands GMA
- Carnarvon GMA
- Fitzroy GMA.

Future management arrangements will be specified in the units and sub-areas of the groundwater management areas.

These five groundwater management areas will effectively replace the existing Fitzroy and Callide subartesian areas, and those parts of the existing Highlands and Great Artesian Basin subartesian areas that are located in the Fitzroy Basin that are currently declared and managed under the *Water Regulation 2002*.

GMAs are divided into sub-areas and groundwater resources can be assigned as units to provide for effective management at the scale required. Schedule 4 of the new draft plan provides maps of sub-areas. The new draft plan will provide for management arrangements in each of the GMAs as summarised below.

### 3.6.1 Callide GMA

Four sub-areas have been established within the Callide GMA as depicted in Schedule 4 Maps A, B, C and D.

- Map A—Upper Callide groundwater sub-area
- Map B—Lower Callide groundwater sub-area
- Map C—Prospect Creek groundwater sub-area
- Map D—Don and Dee groundwater sub-area.

The new draft plan also provides for improved management of subartesian groundwater in the area in the eastern section of the Callide GMA crosshatched on the map in Schedule 3 and referred to as the Callide Groundwater Notification Area. This area was not previously declared under the *Water Regulation 2002* and no licences were required.

The new draft plan provides for notification of groundwater works existing on the date of the moratorium (December 2010) and the subsequent licensing to authorise the take of groundwater in this area. Licences will also be required for any new take of groundwater in the Callide Groundwater Notification Area other than for stock or domestic purposes. It will be necessary to obtain a volume of water and a licence through the release of unallocated water under a process to be defined in the Fitzroy ROP.

The Callide GMA contains two groundwater units. Callide Groundwater Unit 1 contains the alluvial aquifers (quaternary alluvium) and Callide Groundwater Unit 2 contains the remaining aquifers not contained in Callide Groundwater Unit 1. The new draft plan provides for up to 500 ML from each of the strategic and general reserves of unallocated water from Callide Groundwater Unit 2. There are no reserves of unallocated water from Callide Groundwater Unit 1.

The new draft plan will provide for water sharing rules in the Don and Dee groundwater sub-area and these will be specified in an amended Fitzroy ROP.

The more specific issue of groundwater management for the Callide Valley alluviums which are contained within the Upper Callide, Lower Callide and Prospect Creek groundwater management sub-areas and the Callide Valley Water Supply Scheme is discussed in Section 3.6.6.

### **3.6.2 Isaac–Connors GMA**

One sub-area is to be established within the Isaac–Connors GMA as depicted in Schedule 4 Map E–Isaac–Connors alluvium groundwater sub-area. The new draft plan provides for a strategic reserve of 450 ML from this groundwater sub-area. The new draft plan also provides for a strategic reserve of 250 ML and a general reserve of 750 ML for the areas of the Isaac–Connors GMA that are not part of the Isaac–Connors alluvium groundwater sub-area.

For management purposes the Isaac–Connors GMA has been divided into two units:

- Isaac–Connors Groundwater Unit 1 contains aquifers of the quaternary alluvium
- Isaac–Connors Groundwater Unit 2 contains all subartesian aquifers within the Isaac–Connors GMA not included in Isaac–Connors Unit 1.

The Isaac–Connors GMA is predominantly the Highlands subartesian area declared under the Water Regulation 2000. It has been extended to provide for improved management of subartesian groundwater in a relatively small area in the north of the Isaac–Connors GMA, crosshatched on the map in Schedule 3 and referred to as the Isaac–Connors Groundwater Notification Area. This area was not previously declared under the Water Regulation 2002 and no licences are currently required.

The new draft plan provides for notification of groundwater works existing as of specified dates within the extended area of the Isaac–Connors GMA and the subsequent licensing for the take of groundwater in this area. The specified dates for determination of existing works are:

- for Isaac–Connors Groundwater Unit 1 in the Isaac–Connors Groundwater Notification Area—groundwater works in existence as of 15 December 2006
- for Isaac–Connors Groundwater Unit 2 in the Isaac–Connors Groundwater Notification Area—groundwater works in existence on the date of the moratorium (December 2010).

Licences will also be required for any new take of groundwater for purposes other than stock or domestic in the Isaac–Connors Groundwater Notification Area. It will be necessary to obtain a volume of water and a licence through the release of unallocated water under a process to be defined in the Fitzroy ROP.

The new draft plan will provide for the development of water sharing rules where necessary. Water sharing rules such as announced allocations will provide for management of over extraction from the Isaac–Connors alluvium, including the Braeside borefield south of Nebo.

### **3.6.3 Highlands GMA**

The Highlands GMA contains the bulk of the Highlands declared subartesian area that is currently managed under the Water Regulation 2000. The new draft plan describes two groundwater units within the Highlands GMA:

- Highlands Groundwater Unit 1 contains the aquifers of the quaternary alluvium
- Highlands Groundwater Unit 2 contains all subartesian aquifers within the Highlands GMA other than those contained in Highlands Groundwater Unit 1.

The new draft plan also provides a particular part of Highlands Groundwater Unit 1 as a groundwater sub-area depicted in Schedule 4 Map F—Sandy Creek Alluvium groundwater sub-area.

The new draft plan provides for unallocated water reserves as a strategic reserve of 3 000 ML and a general reserve of 7 000 ML from the Highlands GMA other than the Sandy Creek Alluvium groundwater sub-area. There is to be no additional take of groundwater from the Sandy Creek Alluvium groundwater sub-area.

For additional take of groundwater, it will be necessary to obtain a volume of water and a licence through the release of unallocated water under a process to be defined in the Fitzroy ROP.

### **3.6.4 Carnarvon GMA**

The new draft plan deals with the Carnarvon GMA in its entirety and there are no separate groundwater units or sub-areas for management purposes. The new draft plan provides for a strategic reserve of 250 ML and a general reserve of 1000 ML in the Carnarvon GMA.

For additional take of groundwater, it will be necessary to obtain a volume of water and a licence through the release of unallocated water under a process to be defined in the Fitzroy ROP.

All new works for taking groundwater, including those for stock and domestic purposes, in the Carnarvon GMA will continue to be assessable development of the *Sustainable Planning Act 2009* (see Section 116 of the new draft plan). This is to ensure that any new works do not drill into the underlying Great Artesian Basin aquifers.

### **3.6.5 Fitzroy GMA**

The Fitzroy GMA contains the declared Fitzroy Subartesian Area that is currently managed under the Water Regulation 2000. The new draft plan provides for two groundwater units for management purposes:

- Fitzroy Groundwater Unit 1 containing the aquifer described as modern coastal deposits which contains naturally very saline water that has been used for salt production
- Fitzroy Groundwater Unit 2 containing all subartesian aquifers within the Fitzroy GMA other than those contained in Fitzroy Groundwater Unit 1.

The new draft plan provides for a strategic reserve of 500 ML from the Fitzroy GMA, a general reserve of 20 000 ML from Fitzroy Groundwater Unit 1 (modern coastal deposits), and a general reserve of 2 000 ML from Fitzroy Groundwater Unit 2.

For additional take of groundwater, it will be necessary to obtain a volume of water and a licence through the release of unallocated water under a process to be defined in the Fitzroy ROP.

### **3.6.6 Callide Valley alluvium groundwater**

The need to address groundwater management and in particular the over-allocation of groundwater in the Callide Valley alluvium was highlighted in the December 2006 public information report which accompanied the public notice announcing the intent to include groundwater in the Callide catchment as an amendment to the Fitzroy WRP 1999.

Part of the Callide Valley alluvium lies within the supplemented area (benefitted area) of the Callide Valley Water Supply Scheme operated by SunWater Ltd. In this scheme releases are made to streams from Callide Dam and Kroombit Dam for aquifer recharge. Supplemented groundwater is supplied to holders of interim water allocations with a total allocation for 19 527 ML/a.

In the unsupplemented areas of the alluvium, located upstream and downstream of the water supply scheme supplemented area, groundwater is taken by water licence holders with a total allocation for 17 848 ML/a.

The Callide Valley alluvium has been under considerable stress over a long period both from over-allocation and previous high levels of water use and more recently being subject to drought conditions and generally poor groundwater recharge.

While the total allocation from the alluvium amounts to 37 375 ML/a, the average annual water use over the 10-year period from 1997 to 2007 was 13 500 ML (36 per cent of the total allocation), and the maximum annual use was 16 000 ML (43 per cent of allocation). For the same period, the average supplemented water usage was 9500 ML/a (49 per cent of allocation) with a maximum of 11 700 ML, and the average unsupplemented water usage was 4000 ML/a (22 per cent of allocation) with a maximum of 6000 ML. For the 2008–09 water year, supplemented use was 7700 ML and unsupplemented use was 1200 ML.

It is widely acknowledged that this groundwater system is over allocated and a reduction of the volume allocated to existing authorisations is required to better align the allocation with the available supplies. The allocation levels in the Callide Valley alluvium have been assessed as needing to be reduced by around 50 per cent in order to more effectively manage this resource sustainably.

#### **3.6.6.1 Dealing with the over-allocation of groundwater**

A range of options were considered for reducing the level of allocation. The new draft plan proposes that the allocation volumes will be reduced on the basis of the history of use of each entitlement over the 10-year period from 1997–2007, as

opposed to a uniform reduction. This approach will ensure an increased portion of the available resource for active users where there is access to water. Provision is also made for an additional 5 ML over and above the history of use which ensures those who do not have a record of use will receive 5 ML.

The history of use approach would reduce the total allocation from 37 375 ML/a to around 19 000 ML/a, comprising 12 700 ML/a for supplemented water and 6300 ML/a for unsupplemented water.

The allocation reductions would be put into effect by the conversion of about 273 existing interim water allocations and water licences for groundwater to tradeable water allocations through an amendment to the Fitzroy ROP following finalisation of the new plan.

Reduction of the level of allocation in this way will assist in maintaining water supply to those users who have demonstrated dependency on water to support existing business investments and should lead to a more stable base from which industry in the valley can adjust and grow. Water allocations will allow producers to work with greater security and more flexibility than before.

Importantly this proposed method of allocation reduction has no dependency on the hydrologic groundwater model for the Callide alluvium. This model has been developed to compare aquifer responses over the long-term historical period under the proposed and existing allocation scenarios and to provide a basis for measures for water allocation security and environmental objectives required for the water resource plan.

It is possible that both rainfall and stream flow recharge capabilities may have diminished considerably over more recent times caused by agricultural land use reducing infiltration on the floodplain overlying the alluvium, and though siltation of the in-stream recharge areas. There has been no extended wet sequence of years since the 1970s, which are needed for significant widespread aquifer replenishment, to enable evaluation of potential changes in recharge characteristics and groundwater flow.

For these reasons there are remaining uncertainties associated with current natural recharge characteristics as well future rainfall patterns given highly variable long-term historical rainfall distributions. It follows that there should be some caution regarding the recovery of groundwater levels and improvement in supply for water users in the short to medium term, particularly in those parts of the alluvium with slow recharge responses that are currently under the most stress.

### **3.6.6.2 Volumes for new water allocations**

Chapter 5 Part 3 Division 4 of the new draft plan proposes how the volumes for the new water allocations will be determined through the conversion of existing entitlements to water allocations. These volumes will be the nominal volume for a supplemented water allocation and the annual volumetric limit for an unsupplemented water allocation.

The volume for a new water allocation being converted from an existing authorisation will be the average of the five highest annual water use volumes for the authorisation over the 10-year history of use period from 1997–98 to 2006–07, plus an additional five ML allowance. The total volume will not be more than the nominal entitlement volume for the authorisation being converted.

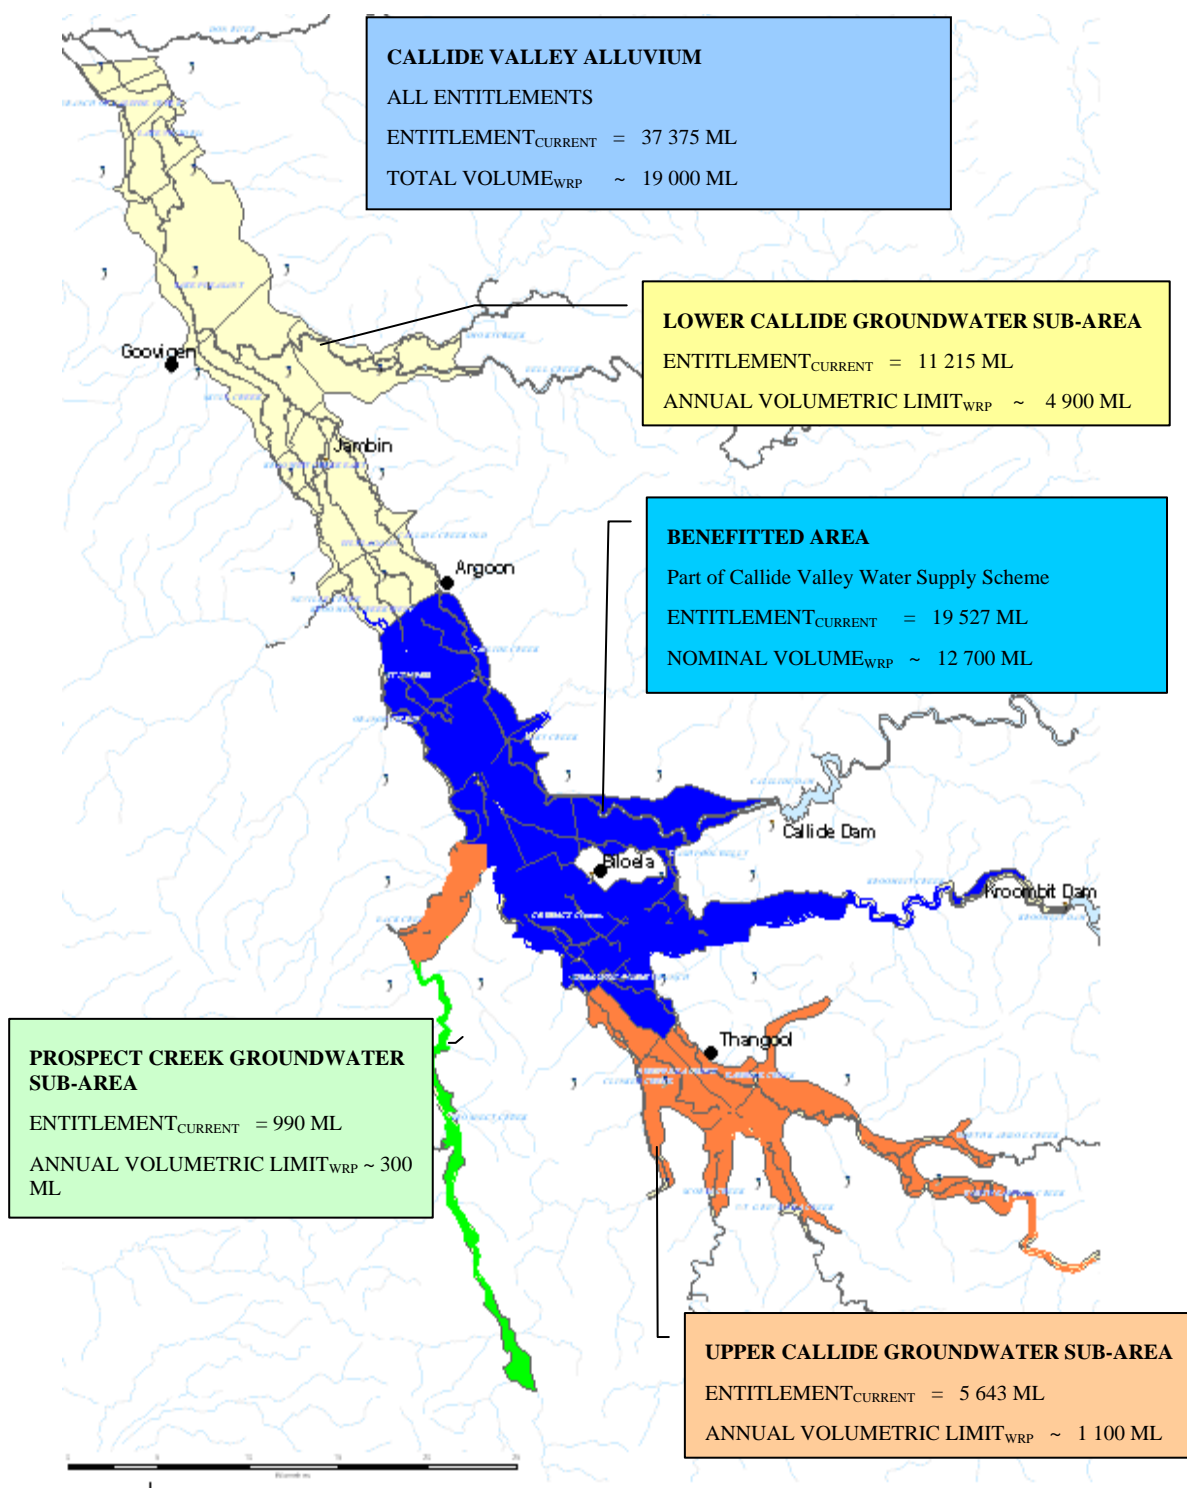

The five ML allowance will only be applied as a benefit for authorisations that existed on the date of release of the new draft plan. The volume determined for an entitlement at the end of the history of use period may also need to be adjusted to account for the effects of any subsequent subdivision or amalgamation of authorisations. These adjustments will be on the same basis that the nominal entitlements associated with the subdivision or amalgamation were determined.

For working out the annual water use for an authorisation during the history of use period:

- Water use in excess of the annual entitlement in a water year that was taken under carry over arrangements will be attributed to the previous year's usage, and water taken under a forward draw arrangement will be attributed to the next year's usage.
- Water use under a seasonal water assignment or temporary transfer arrangement will be attributed to the authorisation from which the water was assigned or transferred.
- Volumes considered as being taken under a stock and domestic accounting arrangement are not included.
- Water use will be adjusted to account for any amalgamation or subdivision of authorisations.

Figure 5 shows an estimate of the total volumes for groundwater allocations to be established based on the history of use approach.

**Figure 5: Callide Valley Alluvium - existing entitlements and approximate future water allocation volumes**

**3.6.6.3 Unsupplemented groundwater water allocations**

Chapter 5 Part 3 Division 3 of the new draft plan proposes how unsupplemented water allocations would be specified. Supplemented water allocations are covered in Section 3.2.1 of this report.

The previous section discusses how the annual volumetric limits will be determined for new unsupplemented water allocations under the new draft plan.

Specifications for unsupplemented water allocations will also include the additional elements of nominal volume and water allocation group. The nominal volume reflects a water allocation's share of the resource and becomes a form of currency for water trading purposes. Each water allocation will belong to a water allocation group for which the plan specifies water allocation security objectives.

The nominal volumes for unsupplemented water allocations will be determined primarily from estimates of the long-term simulated mean annual diversions of groundwater obtained from the Callide groundwater hydrologic model.

It is proposed that water allocations for the Banana Shire Council for Goovigen and Thangool and for the Grevillea and Kooingal rural water supply boards will belong to water allocation groups that are different to the groups for other water allocations in the same locality. This will enable those particular allocations to have preferential access to the available supplies to support improved security of supply under water sharing arrangements (announced allocations) which will be directly related to the prevailing groundwater levels. The water sharing arrangements and water allocation change rules (for trading of water allocations) will be established in a future amendment of the Fitzroy ROP.

It is proposed that the water allocation groups would also reflect the groundwater sub-areas in which the allocations are located. There are three groundwater sub-areas in the Callide GMA where unsupplemented water allocations are to be established, being the Upper Callide, Lower Callide and Prospect Creek groundwater sub-areas. When combined with those allocations which are proposed to have preferential access to the resource, there will be six water allocation groups in total.

Schedule 7 of the new draft plan sets out the water allocation objectives for the unsupplemented groundwater water allocations. The performance indicator is the annual volume probability which equates to the long-term probability of taking the total nominal volume for the water allocation group for a water year. The annual volume probability for the water allocation groups for water allocations in each of the groundwater sub-areas are shown in Table 5.

**Table 5: Minimum annual volume probability for water allocation groups**

Description	Water allocation group	Annual volume probability
Upper Callide groundwater sub-area (existing management sections 4B, 10A, 11A, 11B)	GW1A (Banana Shire Council and Grevillea Water Board)	95%
	GW1B	75%
Lower Callide groundwater sub-area (existing management sections 1, 2A,2B)	GW2A (Banana Shire Council)	95%
	GW2B	75%
Prospect Creek groundwater sub-area (existing management sections 4A)	GW3A (Kooingal Water Board)	95%
	GW3B	85%

These indicators have been established using the Callide groundwater hydrologic model to give an indication of the simulated long-term historical probabilities of water supply for a group of entitlements as a whole. These indicators should not be viewed as an assurance of future performance given the uncertainty of future rainfall, aquifer replenishment and groundwater recovery as previously discussed. In addition the access to groundwater supply is highly spatially variable within the alluvium, more so when storage levels are low.

### 3.7 Providing for Indigenous values

For traditional owners the water resources of the Fitzroy Basin, and the landscape they shape and are formed by, are inseparable from Indigenous spiritual and cultural values. The land and water resources also support the plants and animals that are the source of food for Indigenous communities.

Under the *Aboriginal Cultural Heritage Act 2003*, anyone engaging in any activity has a duty of care to protect areas and objects of significance to Aboriginal people, in accordance with their tradition and history.

In parallel to the *Aboriginal Cultural Heritage Act*, the provisions in the new draft plan support social and cultural interests by protecting dry season habitats such as waterholes, lakes, and other permanent sources of water that may be important to the traditional owners of the area. Additionally, floodwaters will continue to flow to estuarine and marine environments where they will maintain productive traditional fishing interests.

## 4 Strategies for achieving ecological outcomes

Water resource plans provide a framework for the sustainable allocation and management of the water resources of a basin. To that end Sections 14 and 15 of the new draft plan provide for general and specific ecological outcomes that are dependent on the way in which the water resources of the basin are allocated and managed. The new draft plan proposes to achieve these outcomes through a number of strategies.

The new draft plan will build on the strengths of the Fitzroy WRP 1999 and contain a range of strategies that protect the low flow regime and important aspects of in-stream flows, maintain linkages between the floodplain and watercourse and between surface water and groundwater, maintain connectivity along watercourses and protect groundwater levels.

- **Flow Management Strategies:** New draft plan provisions will support the continuation of both the seasonal baseflow and first post-winter flow management strategies as currently managed under the Fitzroy ROP (explained further in 4.1).
- **Interference:** To minimise the impacts of in-stream barriers, future applications to interfere with the flow of water by impoundment will only be considered for enhanced town water supply security, stock and domestic purposes, pumping pools, to satisfy the requirements of an environmental authority or in association with any new release of unallocated water. Applications will be assessed against criteria in the *Water Act 2000* and additional criteria in the new plan. See Section 3.3.4.
- **Flow Regime:** With additional streamflow data and modelling improvements, the hydrologic assessments for the Fitzroy Basin now extend over the historical period from 1900 to 2007 (108 years). The new draft plan's provisions will keep long-term total flows in the Fitzroy River downstream of the barrage above 77 per cent of the mean pre-development flows which was provided for under the Fitzroy WRP 1999.
- **Groundwater:** Groundwater dependent ecosystems across the plan area will be protected by improved management of groundwater and surface water extractions.
  - A total of five groundwater management areas will be established to replace existing declared subartesian areas and provide for additional areas in the Isaac–Connors and Don River subcatchments. See Section 3.6.
  - Limited future additional take from each groundwater management area will be specified, so that total groundwater extractions will be capped.
  - There will be sustainable management of the Callide Valley alluvium arising from an approximate 50 per cent reduction in total volumetric entitlements and water sharing directly related to prevailing groundwater levels. This will promote recovery of ecological values associated with the currently over allocated aquifer system.
- **Environmental Flow Objectives:** The new draft plan will contain environmental flow objectives in the plan area for low flows, medium to high flows, the first post-winter flow and groundwater levels in the Callide Valley alluvium. All future allocation and management decisions will need to be in accordance with these objectives (explained further in 4.2).
- **Maintaining ecological and cultural values of waterholes and lakes by restricting take below natural full supply level** (explained further in 4.3).
- **Effectively limiting the overall volumes of water that can be taken by:**
  - limiting the volumes of water that can be taken using existing entitlements by including volumetric limits
  - specifying additional unallocated water for each subcatchment or groundwater management area and conditioning any future entitlements granted.
- **Climate change and water quality:** The new draft plan has been developed with strategies that should mitigate potential climate change impacts (Section 4.4 of this report) and support good water quality outcomes (Section 4.5 of this report)

### 4.1 Flow management strategies

The environmental water needs at the local scale will be met through the continuation of the seasonal baseflow and first post-winter flow strategies, environmental management rules and the process for dealing with unallocated water. These strategies have been a focus of the resource operations plan and will also guide the water access conditions placed on new licences and existing licences where needed, to ensure that there is water to maintain local natural values.

The seasonal baseflow strategy, which provides for the passing of natural low flow events through water supply schemes and for limiting access by unsupplemented allocations to above certain flow thresholds, will continue under the new draft plan. This strategy supports ecological assets by topping up waterholes, improving water quality and providing connectivity. The strategy will continue to be implemented and amended where necessary to avoid undesirable consequences, such as creating periods of above natural wetness by passing low flow events at the same time as making consumptive releases.

The new draft plan will also continue the first post-winter flow strategy which provides for the passing and maintenance of the first significant flow event after the dry winter period. This characteristic flow of the Fitzroy Basin provides, among other things, opportunities for fish spawning and recruitment, dispersal of fish and other organisms, mixing and flushing of waterholes and temporal diversity in aquatic habitats. Special restrictions are implemented to significantly reduce the potential impact on the first post winter flow by water harvesting operations.

The new draft plan also proposes ecological factors that must be considered when deciding environmental management rules and process for releasing unallocated water. These include consideration of water that is required to maintain:

- the connectivity of low flow habitats throughout the river system
- the connectivity between the stream and its adjacent floodplain and riverine environments
- the seasonality of flows, including periods when there would naturally be no flow
- the replenishment of refuge pools, including waterholes
- surface and subsurface flows, ecosystems and habitats associated with groundwater sources
- the occurrence of the first-post winter flow.

Additionally, it is intended that the amended Fitzroy ROP will require an approved land and water management plan for any new irrigation entitlements to ensure that water use practices are ecologically sustainable.

## **4.2 Securing environmental flows at catchment and aquifer scales**

The new draft plan limits water diversions through the specification of environmental flow objectives. These objectives essentially lock in minimum levels of acceptable change from the natural flows for different stream flow or aquifer characteristics that are important in supporting river or aquifer health.

The environmental flow objectives basically help to maintain flows in streams and aquifers to support non-consumptive uses within the basin and ensure the maintenance of environmental assets.

When partnered with the water allocation security objectives, the environmental flow objectives protect both the water users and the environment from, for example, the effects of any trading that may occur, or any infrastructure operational rules established under the resource operations plan.

The surface water environmental flow objectives in the new draft plan were developed through a hydrological simulation of stream flows and water resource development supported by the new draft plan over a 108-year period from 1900 to 2007. The environmental flow objectives are expressed for performance indicators covering low, medium and high-flow characteristics and the characteristic first post-winter flow event, which are listed in Chapter 4 Part 1 Divisions 1 and 2 of the new draft plan.

The surface water environmental flow objectives specified in Schedule 6 Parts 1 to 3 of the new draft plan, are intended to support flow patterns that mimic the natural wet and dry seasonal river cycles. To that end, the surface water objectives range from setting minimum values for times when the river levels should be low through to consideration of the frequency of floodplain inundation.

The groundwater environmental flow objectives in the new draft plan were developed based on recommendations from the groundwater dependent ecosystem assessments. They were then quantified using a hydrologic simulation of aquifer levels and water resource development in the Callide Valley Alluvium supported by the new draft plan over a 108-year period from 1900 to 2007.

Groundwater objectives aim to keep the watertable levels above specified low levels (Schedule 6 Part 4 provides the EFOs for nodes in the Callide groundwater management area).

Environmental flow objectives provide for sustainable development opportunities while recognising existing development and water use throughout the basin.

Table 6 shows the environmental flow objectives in the new draft plan for the mean annual flows as a percentage of the pre-development flow pattern at various nodes in the Fitzroy Basin. It is important to note that these values are based on an assessment of the basin stream flows and proposed level of water resource development, including volumes of unallocated water, supported by the new draft plan over the 108-year period from 1900 to 2007. As long-term statistics, these values should not be viewed as necessarily typical of each year or future years.

**Table 6: Draft plan mean annual flows as a percentage of pre-development flows**

Location	Mean annual flow	
	Pre-development	Draft plan
Fitzroy River at Barrage	5 941 000 ML/a	77%
Dawson River at Beckers	1 027 000 ML/a	65%
Don River at Rannes	258 000 ML/a	85%
Dawson River at Taroom	383 000 ML/a	90%
Mackenzie River at Tartus	4 049 000 ML/a	80%
Isaac River at Yatton	2 270 000 ML/a	90%
Connors River at Pink Lagoon	1 585 000 ML/a	90%
Mackenzie River at Bingegang	1 784 000 ML/a	70%
Comet River at Comet (10.8 km AMTD)	489 000 ML/a	80%
Theresa (Retreat) Creek at Main Road	355 000 ML/a	90%

### 4.3 Maintaining ecological and cultural values of waterholes and lakes

Natural waterholes and lakes are important parts of watercourse ecology because the water they hold when stream flows cease provides refuge for many plants and animals throughout the dry periods. For Traditional Owners, they are culturally significant as focal points for ceremonies and activities such as hunting and fishing. They are also important for stock and domestic water uses, particularly in dry times.

The new draft plan allows existing users to continue to take water from natural waterholes or lakes under existing conditions. New entitlements to take water from natural waterholes or lakes will limit drawdown to not more than 0.5 metres below full supply level. This ensures that their functioning as a dry-season refuge for plants and animals, or special place for traditional owners, continues.

### 4.4 Addressing the potential impacts of climate change

Water resource plan development accommodates long-term environmental considerations and encompasses the natural variability of Queensland's climate and subsequent availability of water resources.

In developing the new draft plan, the hydrologic modelling included three climate change cases—90th percentile (driest), median (best estimate) and 10th percentile (wettest), based on a high emissions scenario to the year 2050. Information from the Queensland Climate Change Centre of Excellence was used for the modelling. The results produced from the climate change modelling were utilised in the Stage 2 environmental assessment report to assess the potential impacts of climate change on selected environmental assets. See Section 7.2.3 of this report for more information.

The main potential climate change impacts identified by the assessments include general decreases in stream flows, small increased risk to riparian vegetation communities in some areas, low risk to the values associated with waterhole habitat and decreases in the reliability of medium priority water allocations and unsupplemented water diversions.

The strategies provided in the new draft plan to help address these potential impacts are as follows:

- seasonal baseflow and first post-winter flow environmental flow objectives and strategies will maintain waterholes and ecological assets with critical links to low flows
- provision for the setting of appropriate thresholds for new licences to take water in unsupplemented areas to protect existing water users and low flows, which will protect environmental assets
- lower overall unallocated water reserves to protect high flow environmental assets

- provision for the expansion of water trading markets to allow more water users more opportunities to manage supply risk.

The climate change assessments undertaken are discussed further in Chapter 7.

## 4.5 Maintaining and improving water quality through flow management

The flow regime can have an important role in determining the impacts of catchment inputs and in-stream processes on water quality. Factors such as volume, duration and timing of flows have considerable bearing on water quality, with baseflows and medium to high flows being important for:

- removal and dilution of pollutants
- mixing of the water column
- breakdown of stratification and reducing potential for blue-green algal blooms
- scouring sediments
- maintaining refugial waterhole water quality.

The Fitzroy WRP 1999 and Fitzroy ROP contain strategies and rules to support good water quality and mitigate event-based water quality issues. Strategies in the new draft plan will further support good water quality.

- Environmental assessments showed that the seasonal baseflow and first post-winter flow strategies implemented under the Fitzroy ROP in response to environmental flow objectives in the Fitzroy WRP 1999, support good water quality. These strategies are proposed to be continued under the new draft plan.
- Broad strategies and operational rules provided by the Fitzroy WRP 1999 and Fitzroy ROP helped mitigate water quality issues that followed the discharge of Ensham Mine floodwater in 2008. The operators of Ensham Mine were able to access the water market to secure seasonal assignment of water allocations to dilute poor quality water contained in pits to an acceptable level for discharge to the Nogoia River. To further assist with real time responses to potential water quality issues, it is proposed that the amended Fitzroy ROP consider more responsive rules for stream management and infrastructure operating rules.
- With regard to the Environmental Protection (Water) Policy 2009 (EPP Water), draft environmental values and water quality objectives have been developed in collaboration with the Fitzroy Basin Association and key stakeholders. It is highlighted that these are not yet prescribed under Schedule 1 of the EPP Water. The new draft plan provisions are expected to support and maintain the current condition of the ecological assets and estuary while supporting good water quality outcomes consistent with the principles of the EPP Water.

It is important to note that while water resource plans can support good water quality outcomes, there are many other pressures on water quality that are external to water resource planning provisions. Such pressures include climate patterns, land use and management, riparian vegetation condition and authorities to discharge under the Environmental Protection Act.

The environmental assessment provides more information on how the Fitzroy WRP 1999 provided for the maintenance and improvement of water quality.

## 5 Monitoring and reporting requirements

Monitoring and reporting, required under the Water Act, will provide a valuable tool for assessing and reviewing the effectiveness of the final plan. The information gathered will also contribute to the growing body of knowledge about our river systems and will assist in the next 10-year review of the plan.

The new draft plan provides for a monitoring program for general and ecological provisions. General water monitoring will focus on:

- streamflows
- the taking and diverting of water
- releases from water storages
- water quantity for water storages, including inflow, storage volume or level and outflow
- groundwater levels.

Natural ecosystem monitoring will focus on:

- volume, frequency, duration and timing of stream flows
- information on hydraulic habitat requirements of ecological assets in the plan area.

In addition, continuing and extending the requirements for notification of existing and new overland flow works in the Fitzroy Basin will provide for improved assessment of the current levels of overland flow development and will provide a basis for monitoring new development. In addition, monitoring groundwater developments, including through records of water bores drilled and notifications received from the Isaac–Connors and Callide groundwater notification areas will also assist in assessing groundwater development in the Fitzroy Basin. This data will be used to assess the effectiveness of the plan and resource operations plan in meeting objectives.

The monitoring programs will be conducted by the chief executive or other relevant state agencies and by operators of infrastructure under the resource operations plan. Other monitoring programs considered relevant by the chief executive may also be undertaken.

Operators of infrastructure such as SunWater, as the resource operations licence holder for the Nogoia Mackenzie, Dawson and Lower Fitzroy water supply schemes, will be required to report annually to the chief executive on the monitoring programs implemented for the respective storages and other infrastructure. They will also need to provide periodic operational reports on the management of allocations, stream flows and other matters. Some aspects will require more regular reporting and this will be determined under the resource operations plan.

The minister will report annually on the effectiveness of the implemented resource management strategies in achieving the plan's outcomes.

### 5.1 Measuring (metering) devices

Metering is currently being rolled out in the Fitzroy Basin plan area under the statewide metering policy in line with the state's commitment to the National Water Initiative. Metering of additional water entitlements in the plan area will benefit the development of future plans.

The new draft plan proposes that measuring devices be required for water allocations, interim water allocations and water licences. The installation of measuring devices will continue to occur as part of the statewide metering program under the Water Regulation 2002.

Metering provides the information needed to ensure that water users comply with the conditions of their water entitlement. These devices also provide accurate water use data which may help users improve their water resource management and water use efficiency.

By accurately knowing the volume and location of take, metering will support and improve future planning activities. The information gathered will be integrated with other knowledge to improve our understanding of how the water resources in the plan area support the rural economy, communities and the natural environment.

## 6 Implementing and amending the new plan

### 6.1 Amending the Fitzroy ROP

The final plan will be primarily implemented through amendments to the Fitzroy ROP. The amendment of the Fitzroy ROP is the responsibility of the chief executive for the Department of the Environment and Resource Management rather than the minister, as stated in Section 95 of the Water Act.

The department will prepare the draft amendment to the Fitzroy ROP in consultation with water users, water infrastructure operators and other stakeholders. On its completion, the draft amendment to the Fitzroy ROP will be released for public comment and a formal submissions process prior to finalisation.

#### 6.1.1 What the Fitzroy ROP will do

Amendments to the existing Fitzroy ROP will establish additional or amended arrangements for consistency with the strategies contained in the new plan. Among other things the Fitzroy ROP amendments will:

- convert existing authorisations to supplemented water allocations to take water in the Callide Valley Water Supply Scheme
- convert existing authorisations to unsupplemented water allocations to take water in the:
  - alluvium of the Upper Callide, Lower Callide and Prospect Creek groundwater sub-areas within the Callide groundwater management area
  - Nogoa River from the upstream limit of Fairbairn Dam at AMTD 737.5km to its junction with Theresa Creek
  - Theresa Creek from its junction with Retreat Creek at AMTD 15.0km to its junction with the Nogoa River
  - Retreat Creek, including its anabranches, from its junction with Kettle Creek at AMTD 23.6km to its junction with Theresa Creek
  - the Comet River, including its anabranches, from Lake Brown gauging station AMTD 199.2km to its junction with the Nogoa River
  - the Dawson River from the upstream limit of Glebe Weir at AMTD 356.5km to its junction with the Mackenzie River, including sections of tributaries where Dawson River flows are accessible
  - the Dawson River from Utopia Downs gauging station at AMTD 453.5km to the upstream limit of Glebe Weir at AMTD 356.5km, including sections of tributaries where Dawson River flows are accessible
- determine environmental rules, infrastructure operating rules, water sharing rules, water allocation change rules and seasonal water assignment rules for water in the Callide Valley Water Supply Scheme
- establish licences to take groundwater in the Callide groundwater notification area and the Isaac–Connors groundwater notification area
- establish revised processes to deal with unallocated water available for future water requirements in the plan area
- establish a process for granting or amending water licences for taking overland flow water
- implement the monitoring requirements.

The structure of the Fitzroy ROP will also be updated for consistency with recently developed resource operations plans.

#### 6.1.2 Timeframes for implementation

The preparation of a draft amendment to the Fitzroy ROP will commence after the release of the draft water resource plan. This timing will expedite the finalisation and implementation of the amendment to the Fitzroy ROP. It is expected that the amendment to the Fitzroy ROP will be completed within two years of plan finalisation.

The actual timeframe will depend on the community response to the draft water resource plan, the draft Fitzroy ROP amendment, and resolution of any issues that arise from these plans.

## **6.2 Amending or replacing the water resource plan**

Water resource plans have a statutory life of 10 years under the Water Act. The review and development of the next water resource plan is expected to begin after the final plan has been in place for seven years. However, the plan can be amended during its 10-year life. The new draft plan allows for specific minor amendments to be made. These types of amendments would allow improved ongoing implementation of the water resource plan and are considered to have no effect on achieving the outcomes of the plan. In particular circumstances, the Water Act also allows for more significant amendments or the replacement of the plan during the 10-year period.

Water resource plans are developed through using the best available information and seeking the views of stakeholders through an extensive community consultation process. While they are designed to achieve a range of outcomes and provide certainty over their 10-year life, it is prudent to cater for possible changed circumstances or new information, which may show that the plan outcomes are not being achieved.

The new draft plan directs the minister to consider amending the plan or preparing a new plan if, for example, water entitlements are not sufficient to meet water needs or if the general or ecological outcomes are not being achieved.

## 7 How the new draft plan was developed

Under the water resource planning process, the minister has a clearly defined set of requirements within which there is flexibility to assess and address the future needs of each individual plan area and its communities.

The Fitzroy WRP 1999 was the basis upon which the new draft plan could be developed. Strategies in the Fitzroy WRP 1999 and their implementation through the Fitzroy ROP were examined for their effectiveness in meeting outcomes. The aim of the new draft plan was to build on the Fitzroy WRP 1999 and improve or include additional strategies where required.

Technical assessments—hydrologic, environmental and socioeconomic—and community consultation were central to preparing this new draft plan.

While these technical assessments provide a comprehensive snapshot of the many factors that must be considered in developing the new draft plan, input from the community in the plan area ensures that they are viewed correctly in the broadest social context.

### 7.1 Input from the community

Community views were sought formally through the submission period at the commencement of the planning process and through the establishment of a community reference panel. The department also sought views from relevant community and stakeholder groups, as well as from individuals.

#### 7.1.1 The community reference panel

The minister is required, under the Water Act, to establish a community reference panel for the water resource planning process that includes representatives from cultural, economic and environmental interests in the plan area. Although the panel is not a decision-making body, it plays a key role in advising the minister on the views and opinions of the community.

The Fitzroy Basin community reference panel (CRP) was appointed by the minister in October 2008. The panel consisted of 19 members reflecting a diverse set of interests including grazing, irrigated agriculture, mining, industry, commerce, conservation, local government, Traditional Owners, water service providers and the broader community. Additionally, given the large size of the plan area, representation across geographical areas was also included.

The extensive interests represented on the panel were reflected in the breadth of views that were expressed. This, in turn, generated a wide range of factors for the minister to consider in preparing a new draft plan containing the balance of provisions needed to sustainably allocate and manage the water resources of the area.

Representatives from relevant government agencies were also on hand at meetings to support proceedings by providing technical advice and contributing a whole-of-government dimension to the panel's agenda.

The panel met three times during development of the new draft plan to review information and advise the minister on water resource issues of importance to the catchment community. The panel will be reconvened for a fourth meeting to be briefed on the contents of the new draft plan.

The panel provided diverse views and comments on the key areas referred to below details of which can be found in the Fitzroy Basin CRP report. Importantly the different views and comments should not be perceived as a consensus panel view, nor was consensus expected, given some of the potentially more contentious and complex issues. While some of the input provided by the CRP may not relate directly to considerations for the new plan and the Fitzroy ROP, they provide important background information for water management in the broader resource management context.

- **Unsupplemented water management:** CRP comments focused on considerations in relation to prioritising areas for further conversions of existing water licences to tradeable water allocations and for determining conversion parameters for conversions and amendment of existing licences.
- **Unallocated water:** Diverse opinions were put forward about provisions for unallocated water and how and when the unallocated water should be made available. The influences of climate change, expectations for future water infrastructure development, urban water provision and water quality issues were topical issues for the CRP.
- **Overland flow water:** The overland flow management provisions in the existing plan were considered by the CRP and suggestions included changes to the existing arrangements and the need for better community understanding of their regulatory obligations.
- **Groundwater management:** The CRP acknowledged and was briefed on the earlier work done by community reference panels previously established to provide advice in relation to groundwater management for the Callide subcatchment and for the Isaac–Connors subcatchment. Based on background of the work in those areas, the CRP focussed on groundwater management elsewhere and provided suggestions on matters for consideration.
- **Mining:** Given the extensive mining activity undertaken and proposed in the basin, comments in relation to mining

issues were raised under the previous topics. However the CRP also offered more specific comment on the need for more consistent arrangements for water access for mining with those that apply to the agricultural sector, as well comment on matters related to water trading and mining impacts.

- In-stream impoundments: The CRP commented on requirements in the new draft plan for the development of new in-stream storages. Views were given about where new developments should be limited and relevant issues to consider including environmental and cultural heritage.
- Water quality: Water quality was an important issue for the CRP. The panel discussed a wide range of water quality issues and requested that the new WRP support water quality objectives.
- Other matters: Other comments raised by CRP members included support for continued expansion of water use metering, needing to account for climate change in hydrologic assessments, and consideration of native title and cultural heritage.

Community reference panels were formed previously for the Callide and Isaac–Connors groundwater amendments to the Fitzroy WRP 1999. When the groundwater amendments were rolled into the development of the new draft plan all planned panel meetings for these panels had been finalised. Panel members were invited to nominate for the Fitzroy Basin CRP.

For further information the Isaac–Connors and Callide CRP reports are included as appendices in the Fitzroy Basin community reference panel report.

The community reference panel for groundwater in the Callide subcatchment was initially established in 1997 and five meetings were held by October 2008, concluding the planned meetings for the panel. The panel put considerable effort into providing views and comments about groundwater management, in particular how over-allocation of the groundwater resources of the Callide Valley alluvium might be addressed in order to sustainably manage groundwater into the future. This was a confronting challenge and the feedback and comments provided by the panel about possible management options was an important input for further consideration and development of the proposals set out in the new draft plan for community to consider and provide feedback to the minister

The community reference panel for groundwater in the Isaac–Connors subcatchment was established in 1997 and four meetings were held by December 2008, concluding the planned meetings for the panel. The panel discussed a wide range of management issues for groundwater in the Isaac–Connors subcatchment with the main focus on the alluvial aquifers. The panel supported and endorsed policy directions for consideration for groundwater in this area in relation to trading of water, management areas, notification and licensing outside of the existing declared groundwater area and unallocated water provisions. The contributions made by the panel have provided a sound basis on which to develop proposals for groundwater management in the Isaac–Connors for the new draft plan.

### **7.1.2 Additional community consultation**

The minister is required, under the Water Act, to conduct a formal submission process on the intention to prepare the new draft plan. Two formal submissions processes were undertaken during the development of the new draft plan. Submissions were sought both at the commencement of the water resource planning process and following the release of a further notice of intent to include groundwater in the plan area. All submissions received were considered in the development of the new draft plan along with submissions received on the notices of intent for the Isaac–Connors and Callide groundwater amendments to the Fitzroy WRP 1999. The submissions provided the minister with a perspective on community support and their views regarding the new draft plan. Views submitted included that some management strategies of the Fitzroy WRP 1999 has not been implemented through the Fitzroy ROP e.g. overland flow water, the impacts of mining (e.g. coal seam gas water take, mine de-watering and overland flow capture), expansion of water trading and communication and consultation.

While the submissions processes and the community reference panel were the main forms of consultation, other methods of gauging community perspective were also employed. These included:

- Departmental staff attended a number of public information sessions in June 2008 to discuss the notice of intent to prepare a new draft plan.
- At stages through the planning process, departmental staff met with various stakeholders to discuss the development of the new draft plan.

Additional information sessions and stakeholder meetings will be held during the consultation period, which will begin with the new draft plan's release. This will promote informed debate and active input through formal submissions to the plan's finalisation.

## 7.2 Technical assessments

Socioeconomic, environmental and hydrologic technical assessments were undertaken to support the preparation of the new draft plan.

The community reference panel members reviewed and provided comments on the draft technical reports for the environmental, and socioeconomic assessments.

### 7.2.1 Hydrologic assessment

Hydrology—the study of water as it moves through the water cycle—is fundamental to learning about the relationship between flows and the environment. For the water resource planning process, the hydrologic assessment relies substantially on mathematical modelling of streamflows and groundwater behaviour.

The department's water assessment group had developed an integrated quantity quality model (IQQM) for surface water for the Fitzroy WRP 1999 and Fitzroy ROP. The IQQM is a computerised daily time-step hydrologic model, developed to simulate stream flows in the plan area. The model simulated stream flows over a 95-year period—from 1900 to 1995.

For the new draft plan a new IQQM has been developed and the simulation period now extends over a historical period from 1900 to 2007 (108 years). The new model also incorporates a number of key improvements including:

- better representation of dams, weirs and water entitlements
- improved derivation of historical streamflows by using the latest modelling techniques
- improved capability to represent operational management rules
- starting the model operation from 1889 to ensure more realistic conditions, particularly for major storages, at commencement of the 1900–2007 simulated period
- improved spatial representation of flow and surface water licences in the Callide subcatchment.

Hydrologic modelling allowed for a comparison between simulated pre-development flows—how streams would behave if there were no dams or other water infrastructure and no water extraction—and different development levels. This demonstrated the potential effects of differing development levels on stream flows and existing water users. The model is also used to test the performance indicators against which the objectives in the new draft plan are assessed.

Scenarios have been developed for pre-development, current development and full development (new draft plan provisions).

The new draft plan will maintain the mean annual flow past the Fitzroy Barrage at a level of 77 per cent of mean pre-development flows as per the Fitzroy WRP 1999. These flows assume full utilisation of existing entitlements and the full development and use of the proposed provisions for unallocated water over the 108 year simulation period.

Further information on the IQQM model for the Fitzroy Basin can be found in the hydrology report.

A Callide groundwater model has also been developed to assess groundwater level responses to a range of allocation and management scenarios for the Callide Valley alluvium. Simulations have been undertaken over the same 108 year period as utilised in the Fitzroy Basin IQQM surface water model. The groundwater flow model uses the simulated flows from the Fitzroy Basin IQQM surface water model to assess groundwater–surface water interaction and groundwater recharge potential. This leads to better capability to simulate groundwater level behaviour for different management scenarios.

#### 7.2.1.1 Climate change modelling

As part of the development of the new draft plan, climate change sensitivity cases were run to assess the areas of the Fitzroy Basin that are sensitive or vulnerable to climate change. For the purpose of the climate change modelling, the IQQM model developed for the Fitzroy ROP (with a simulation period of 1900–1995) was extended with flow sequence data to 2007. The IQQM model was then modified with information supplied by the Queensland Climate Change Centre of Excellence. The results from the climate change modelling were compared across the flow regime and across the basin.

For this assessment the 2050 A1FI emissions scenario was chosen. This is a higher emissions scenario. Eleven global climate models (also known as general circulation models) were chosen based on their ability to predict changes to rainfall. These global climate models were ranked based on their impact on the rainfall. Previous studies have shown that ranking global climate models by rainfall produces the same results as ranking by flows.

Three global climate models were chosen that represent the 10th (wetter), 50th (median) and 90th (drier) percentile cases of climate change. The 50th (median) percentile case represents the most likely impact from climate change and the 10th (wetter) and 90th (drier) percentile cases give an indicator of the range. The climate change cases were applied to two development scenarios: existing levels of infrastructure (current development) and full development including new infrastructure such as Nathan Dam.

The results from the hydrologic assessment indicated the potential for decreases in the availability of water for medium priority water allocations and unsupplemented water diversions under climate change conditions.

The environmental assessment, discussed below in Section 7.2.3, used the results produced from the climate change modelling to assess the potential impacts of climate change on selected environmental assets (Chapter 8 of the Stage 2 Environmental Assessment contains further information). The main potential impacts identified by this assessment were as follows:

- small increase in the risk of local population failure of barramundi
- no increase in the risk of local population failure of king threadfin salmon
- small increase in risk to riparian vegetation communities through a lower average maximum yearly inundation
- low risk to the values associated with waterhole habitat
- a small decrease in the number of high catch years in off-shore reef fisheries under a full development scenario and a slight increase in high catch years under the current development scenario.

The strategies in the new draft plan that will help to address these potential impacts are as follows:

- conservative unallocated water reserves to protect environmental assets and existing water users
- conversion of water licences to water allocations which will allow for the expansion of water trading markets
- seasonal baseflow and first post-winter flow environmental flow objectives that will help to maintain waterholes and ecological assets with critical links to low flows and the first post winter flow
- provision for the setting of appropriate thresholds for new licences to take water in unsupplemented areas to protect existing water users and low flows, which will help to protect environmental assets.

## **7.2.2 Socioeconomic assessment**

The socioeconomic assessment to inform the development of the new plan was carried out in two stages. The two socioeconomic assessments prepared for the Callide and Isaac–Connors groundwater amendments to the Fitzroy WRP 1999 are included as appendices to the Stage 2 report.

### **7.2.2.1 Stage 1 Baseline Report**

This report provides a basic economic, social and water resource management profile of the plan area. A summary of socioeconomic findings from the report include:

- The regional resources boom has been the single biggest factor driving the region's rapid population growth and economic development in recent times.
- Some mining employment practices, such as contract work and fly-in/fly-out or drive-in/drive-out arrangements, have contributed to economic growth in non-mining areas. There is also evidence that local industries struggle to compete against mines in the local labour market. The increase in people moving to Queensland to take up jobs associated with the mining industry will place pressure on water infrastructure supplying urban communities.
- The water resources in the Fitzroy Basin are also significant to the history and culture of the Indigenous population which comprises about five per cent of the total population, a percentage slightly higher than the Queensland figure of 3.3 per cent.
- Water availability is only one of the factors that can potentially constrain the development of water using sectors (urban, industrial or rural). Other factors include land availability, market conditions and the availability of other business inputs such as skilled labour and capital.
- Post global financial crisis market prospects for water-using industries may improve. Better use of available supplies, improved water use efficiency, utilisation of currently unallocated water where available, water trading, and construction of the additional water infrastructure projects nominated in the Central Queensland Regional Water Supply Strategy (CQRWSS) will be required to meet projected increased demands.

- Survey evidence suggests that the permanent trading of water allocations provided under the Fitzroy WRP 1999, and implemented through the Fitzroy ROP 2004 has worked well in the Fitzroy catchment. Participants are able to dispose of water allocations surplus to requirements or acquire additional water allocation with relative ease.
- There are important environmental assets in the Fitzroy catchment. These environmental assets help to support and maintain vital industries such as ecotourism and commercial fishing as well as provide outdoor recreation activities for the community.

### 7.2.2.2 Stage 2 Assessment Report

This report builds on the Stage 1 report and is a qualitative evaluation of the socioeconomic effectiveness of the Fitzroy WRP 1999 strategies in meeting its outcomes. It also provides an assessment of the socioeconomic implications of water management issues for consideration in developing the new draft plan. The report tabulates findings from these assessments and provides the potential outcomes and assessment tools for consideration in the new draft plan. The findings included ensuring security for existing authorisations and entitlements, improving specification of entitlements, providing for flexibility in water management, including water-use efficiency, providing for non-consumptive uses and providing for future water requirements.

Summarised findings regarding the effectiveness of the Fitzroy WRP 1999 strategies in meeting its four outcomes were:

- security for water users—the Fitzroy WRP 1999 strategies have:
  - increased security for supplemented entitlements by establishing water allocations in all water supply schemes except the Callide Valley Water Supply Scheme where interim arrangements continue
  - increased security and definition for unsupplemented water entitlements from the Nogoia, Mackenzie and Fitzroy Rivers including the creation of water markets in three water management areas. A recent amendment of the Fitzroy ROP to provide for trading between medium and high-priority water in the Nogoia Mackenzie Water Supply Scheme to provide for anticipated urban, mining and industrial development further enhances water trading options
  - managed overland flow water with some transitional provisions.
- security for holders of resource operations licences—the Fitzroy WRP 1999 strategies have delivered certainty to water supply providers through establishment of water sharing and operational rules in water supply schemes
- further water-related development in the plan area—the Fitzroy WRP 1999 strategies have provided for reserves of unallocated water and water markets to allow for future development
- environmental water requirements for natural ecosystems in the plan area—the Fitzroy WRP 1999 strategies have delivered effective water management rules to provide for non-consumptive uses. The effectiveness of this outcome is further analysed in the environmental assessment report.

The Stage 2 report also examined the socioeconomic implications of key water management issues in the Fitzroy Basin. The report looked at key management issues in the context of the National Water Initiative objectives. A summary of key findings and considerations for the new draft plan are as follows:

- Consideration should be given to amending existing licences to include specification of a maximum diversion rate and an annual volumetric limit. Where adequate information is available, such as on trunk streams, consideration should be given to converting additional unsupplemented water entitlements to tradable water allocations.
- Socioeconomic benefits of improved entitlement specification include more certainty for water users, entitlements less open to interpretation, more equitable sharing between all users, and entitlement holders able to make more informed investment and management decisions.
- Socioeconomic benefits of water trading include voluntary participation in water markets which can provide existing water allocation holders the opportunity to restructure or exit enterprises as circumstances change and some opportunity for new developments subject to increased economic return where water moves to higher value uses. It also provides water users with flexibility to manage for uncertainty, such as market conditions, unforeseen events, climate variability and change.
- Consideration should be given to a provision so that mines can apply and pay for unallocated water as an interim measure until an amendment to the Fitzroy ROP to include overland flow water is finalised.
- Consideration should be given to a provision requiring mines to notify details of their existing overland flow works in the same manner as other owners of overland flow storages.
- Consideration should be given regarding the management of groundwater under the new draft plan.

- Consideration should be given to a process to convert groundwater entitlements in the Callide Valley Water Supply Scheme—currently held as interim water allocations—to tradable water allocations and/or other defined entitlements as required.
- Consideration should be given regarding converting unsupplemented groundwater water licences in the Callide Valley alluvium to tradeable water allocations.
- A review and confirmation of the volumes of the unallocated water potentially available in the plan area should be undertaken. This review should recognise the effects of overland flow development and consider providing reserves specifically for government commitments to new infrastructure (a strategic reserve), projects of state or regional significance, town water supplies, and indigenous community projects (a strategic reserve) and a general reserve for any purpose.
- The new draft plan should also consider an unallocated water reserve for the plan area downstream of the Fitzroy Barrage. This area contains nationally significant wetlands adjacent to the estuarine reach of a major river that discharges to the Great Barrier Reef lagoon.
- Strategies will need to be developed in the new draft plan to manage connected surface water and groundwater as a single resource and to return extraction of groundwater from the Callide Valley alluvium to sustainable levels as required under NWI.
- Consideration should be given to providing a water management framework that has regard for the needs of all water users in a catchment that are likely to experience an increase in climate variability:
  - Improved specification of water entitlements and tradable allocations separable from land will provide consumptive water users with flexibility in how they manage and use water
  - The trend towards water users holding a portfolio of water authorisations and entitlements is likely to continue.
  - The recent amendment to the Fitzroy ROP to provide for trading between medium and high-priority supplemented water in the Nogo Mackenzie Water Supply Scheme provides opportunities for consumptive users to develop strategies to deal with climate variability and climate change.

### **7.2.2.3 Callide Socioeconomic Report**

The Callide Socioeconomic Report was conducted as part of the Callide groundwater amendment to the Fitzroy WRP 1999. The purpose of the report was to provide a baseline assessment of socioeconomic conditions and trends of the Callide subcatchment, including associated water needs. The report focuses on the Callide Valley alluvium which is the main aquifer in the subcatchment area. The report also examines the likely economic and social effects of broad reforms arising from the proposed amendment to the Fitzroy WRP 1999. Key findings from this report were:

- The alluvial aquifers associated with Callide Creek and its tributaries form the main primary groundwater resource in the Callide subcatchment. Most of the Callide Valley alluvium is under considerable stress due to high levels of use in the past. The situation has been exacerbated by the more recent extended dry period and the associated lack of recharge to the aquifer. In large parts of the aquifer water levels are at record lows and many entitlement holders have been unable to access useful supplies for some time. The over-allocation of groundwater in this aquifer threatens the long-term sustainability of the resource, the socioeconomic stability of the area, and the health of ecosystems that depend on groundwater.
- The need to return over-allocated systems to environmentally sustainable levels of extraction is a key objective of the National Water Initiative. A secure management framework that helps to ensure the sustainable use of scarce groundwater supplies will bring economic benefits to the area for current and future generations.
- Agriculture, mining, and meatworks are the major employers in the Callide subcatchment. The share of employment in mining is expected to continue to increase.
- The regional resources boom is driving economic growth and economic change in the subcatchment. This is expected to continue.
- Agricultural water users have adjusted from historic use levels to much lower levels of use caused by current water availability. For example, farmers have responded to reduced groundwater availability in a number of ways, including investments in water use efficiency, movement into dryland agriculture, diversification into other crops and movement into niche industries.
- The employment opportunities provided by the resources sector have helped to supplement income levels for some farmers. This is likely to have assisted some farmers facing the financial effects of the drought.
- Groundwater availability could constrain future expansion of the meatworks and could also pressure urban water supplies if there was population growth.

- Improved security through a well defined water allocation framework will enable water users to make informed decisions for management of their businesses. A framework for sustainable groundwater management will reduce groundwater supply risks for all users including the environment.
- Providing for the conversion of water licences and interim water allocations to water allocations would bring real economic and financial benefits to water users. Trading would be likely to contribute to economic growth in the subcatchment by allowing water to move to higher value uses and/or where the demand for water is high. This effect may take some time as people get used to the opportunities provided by water trading.
- The basis for the conversion of groundwater licences and interim water allocations into water allocations is a complex issue. The best economic approach is to use historical water use as the basis for conversion.
- Developing and implementing a sustainable groundwater management framework is likely to assist in achieving socially, economically and environmentally sustainable water use in the subcatchment.

#### **7.2.2.4 Isaac–Connors Stage 1 Economic and Social Assessment Report**

The Isaac–Connors Socioeconomic Report was developed as part of the Isaac–Connors groundwater amendment to the Fitzroy WRP 1999. The purpose of the report was to provide a baseline assessment of socioeconomic conditions and trends of the Isaac–Connors catchment. The report was completed by Marsden Jacob Associates. Key findings from the report were:

- Water use is dominated by mining related activities associated with the increases in coal production. Over the past 5–10 years, the water requirements of mining and associated sectors have grown steadily. In addition, there is a high level of interest in further developing water resources for agricultural purposes.
- The department has received licence applications for an additional 8000 ML of groundwater.
- Recent studies indicate that parts of the groundwater system may be fully committed.
- The Isaac–Connors catchment has experienced rapid population growth in the past five years, primarily attributable to the rapid growth in mining developments.
- Town water requirements are met through a mix of surface water and groundwater systems, depending on location. Much of the population’s water needs are met through the same systems that supply mine requirements. In the longer term the population is expected to decline marginally from the current peak as the development and expansion phase of mining activity concludes and mines move to the long-term operational phase.
- Sectors that are more likely to experience further growth are mining, beef cattle, and irrigated agriculture (particularly fodder to underpin intensive beef production).
- The development of the Burdekin to Moranbah pipeline is likely to meet the short to medium-term requirements of the mining sector and most of the needs of the urban sector. However, the requirements of Nebo township already exceed the sustainable yield of their groundwater source. It is unlikely that supply to Nebo could be augmented without significant investments in infrastructure (e.g. a spur line to other water supply systems).
- Chapter 6 of the report discusses potential options to address future water requirements including Connors River Dam, water use efficiency and unallocated water.

### **7.2.3 Environmental assessment**

The environmental assessment to inform the development of the new plan was carried out in two stages. In addition three technical advisory panel reports had been developed for the Isaac–Connors and Callide groundwater amendments to the Fitzroy WRP 1999.

#### **7.2.3.1 Report 1: Background**

This report sets the context for the Assessment Report (Report 2). The report:

- provides a basic water resource management profile of the Fitzroy Basin
- summarises the environmental provisions contained within the Fitzroy WRP 1999 that were developed with the help of a Technical Advisory Panel with specific knowledge of riverine biology, ecology and geomorphology
- outlines the water monitoring and planning activities that occurred within the Fitzroy Basin:
  - Over the past ten years the department has monitored the aspects of the Fitzroy Basin that are of direct relevance to the Fitzroy WRP 1999, including the quantity and quality of surface and ground water resources, and freshwater and estuarine ecological assets. Additionally, in 2004 the department established the Environmental Flow Assessment Program (EFAP).

- Other government and non-government organisations performed monitoring activities relating to water-storage operation; sediment, salinity and nutrients; fish populations, fisheries catch and estuarine habitat; and assessment of the long-term effectiveness of the Reef Water Quality Protection Plan in halting and reversing the decline in water quality of run-off from Great Barrier Reef catchments.
- summarises the key advances in scientific knowledge of riverine and flow-dependent ecosystems.

A science review panel comprising Mr Ian Jowett (Ian Jowett Consulting—retired from the National Institute of Water and Atmospheric Research Ltd NZ); Professor Richard Pearson (James Cook University); and Dr Leo Duivenvoorden (Central Queensland University) reviewed the report and provided comments for incorporation.

### 7.2.3.2 Report 2: Assessment

This report includes technical assessments and provides considerations for the new draft plan. The report included:

- ecological risk assessments including results from EFAP ecological risk assessment (for current and full development (inclusive of Nathan Dam) scenarios that indicated:
  - for both the current and full development scenarios, 5 out of 14 ecological assets were placed at low risk. Three of these assets were the low flow spawning fish, where persistent and stable low flows in water supply schemes provide greater opportunities for recruitment. Risk to waterholes as refugia in water supply scheme areas is also considered to be low due to top-up flows. Risk to waterholes as refugia in unsupplemented areas, where there are no top-up flows, is higher. Barramundi growth was also considered to be at low risk.
  - Under the current development scenario the following ecological assets were assessed to be at higher risk:
    - floodplain riparian vegetation communities (with emphasis on *Eucalyptus coolabah*)
    - juvenile barramundi (*Lates calcarifer*) recruitment
    - banana prawn (*Penaeus merguensis*) growth
    - high catch years (of fin-fish) at the Capricorn and Bunker groups
    - king threadfin salmon (*Polydactylus macrochir*)
    - wetlands as habitat
    - the population persistence of Fitzroy golden perch (*Macquaria ambigua orientis*).
  - further assessments under the full development scenario where the same assets stated above were again placed at higher risk with increased risk to barramundi year class strength.
  - population viability modelling of the Fitzroy golden perch. This suggests that while no immediate risk exists under the current development scenario, there may be an increased risk under the full development scenario
- a review of the Fitzroy WRP 1999 and Fitzroy Basin Resource Operations Plan 2004 (Fitzroy ROP) environmental strategies and Fitzroy ROP arrangements that indicated that the seasonal baseflow arrangements, the first post-winter flow (FPWF) arrangements and other operational arrangements are generally effective in achieving their ecological intent
- a climate change sensitivity analyses (discussed in Section 7.2.1 of this report)
- options for consideration in the development of the new draft plan which include:
  - additional environmental flow objectives (EFO) and associated Fitzroy ROP arrangements (FPWF and seasonal baseflow) to manage the potential impacts on flow dependent ecosystems and water quality from additional water infrastructure e.g. Nathan and Connors River dams
  - providing for management arrangements to deal with the potential impacts of climate change:
    - apply a conservative approach to the volumes of unallocated water provided for, and stage releases to match demands
    - continue implementing the seasonal baseflow and first post-winter flow objectives and associated Fitzroy ROP arrangements that help maintain low flows, waterholes and ecological assets with critical links to low flows and the first post-winter flow
    - further develop and expand the water trading markets
    - condition any new entitlements arising from the release of unsupplemented unallocated water with appropriate flow thresholds to allow passing of low flows.
  - inclusion of a set of performance indicators (representing no, low, medium and high flows, flow variability and total

flow volumes) to provide for a greater range of flow attributes, represent ecological assets and better align with more recent east coast water resource plans

- for first post-winter flow (FPWF) management:
  - increase the current minimum temperature threshold of 23°C in the Fitzroy WRP 1999 to 24°C for September to help maximise spawning potential for the Fitzroy golden perch
  - temporarily increase the nominal operating levels of storages at the onset of the FPWF period up until the passing of the event to benefit the passing of smaller FPWF events.
  - expand to other existing infrastructure where appropriate.
- more prescriptive specification of changes in the rate of release from storages in the Fitzroy ROP to reduce incidence of fish stranding in tailwater areas
- given the potential for undesirable consequences a strategy is suggested that could assist in responding to event-based water quality issues
- promote maintenance of groundwater dependent ecosystems in the Callide subcatchment and Isaac–Connors catchments by arrangements that may include providing for the:
  - establishment of EFOs with associated nodes and performance indicators
  - provision of more targeted outcomes than those currently specified in the Fitzroy WRP 1999.

A science review panel comprising Mr Ian Jowett (Ian Jowett Consulting—retired from the National Institute of Water and Atmospheric Research Ltd NZ); Professor Richard Pearson (James Cook University); and Dr Leo Duivenvoorden (Central Queensland University) reviewed the draft report and provided comments for incorporation.

### **7.2.3.3 Callide Subcatchment Groundwater Dependent Ecosystem Assessment**

The Callide Groundwater Dependent Ecosystem Assessment was conducted as part of the Callide groundwater amendment to the Fitzroy WRP 1999.

The report was completed by Sinclair Knight Merz (SKM). This report focuses on groundwater dependent ecosystems (GDEs) of the Callide Valley alluvium, which contains the most developed groundwater resource in the plan area.

Assessments were divided into four key areas: wetlands, terrestrial vegetation, river baseflow systems and aquifer ecosystems. Key recommendations for consideration:

- Wetlands: monitoring bores should be established on two selected wetlands, determined in the report to be groundwater dependent. Environmental Flow Objectives (EFOs) should be established at the downstream end of Bell Creek, where numerous wetlands were identified.
- Terrestrial vegetation: all mapped remnant vegetation was within 500 metres of streams, with 80 per cent within 100 metres of a stream. Recommendations include monitoring watertable levels, setting appropriate EFOs and applying setback distances for new bores of 200 metres from major creeks.
- River baseflow systems: these systems comprise lotic (flowing) aquatic ecosystems and riparian ecosystems. It is recommended that setback distances for new bores of 200 metres from major creeks be implemented for new groundwater bores to limit interference to streamflow.
- Aquifer ecosystems and their associated stygofauna: ten bores were sampled by DERM staff for stygofauna (groundwater dwelling invertebrates) and new species of Ostracod and Copepod were discovered at one bore. No specific strategies for stygofauna are being proposed for the new draft plan, because the understanding of the water requirements of stygofauna is in its infancy.
- provisions recommended for inclusion in the draft plan include establishing EFOs at key locations, and utilising existing monitoring bores to monitor wetlands and remnant vegetation sites selected from those identified in the report.

The consultant's report suggests that recovery in groundwater levels will provide an important basis for preservation of GDEs. Groundwater pump setback distances are recommended in the report to protect river baseflow systems and other GDEs.

### **7.2.3.4 Isaac–Connors Groundwater Project Parts A and B**

For the Isaac–Connors groundwater amendment to the Fitzroy WRP 1999, assessments undertaken were the Isaac–Connors Groundwater Project Part A: Conceptual Model for Groundwater and Part B: Assessment of Groundwater Dependent Ecosystems.

The reports were completed by Sinclair Knight Merz (SKM.) Key recommendations from the Isaac–Connors Groundwater Project Part A: Conceptual Model for Groundwater are:

- cap new allocations from the Isaac–Connors alluvial aquifers
- consider reducing groundwater extraction from the Braeside Borefield
- review allocation levels as more data becomes available following metering of extractions
- provide stream buffer zones (setback distances)
- a number of further studies were recommended.

Key recommendations to be considered from the Isaac–Connors Groundwater Project Part B Assessment of Groundwater Dependent Ecosystems (GDEs) are:

- limit further groundwater extractions
- ensure water management arrangements are sufficiently flexible to allow for the large inter-annual variability in groundwater recharge, GDE requirements and human demands
- provision of buffer zones for GDE sites (setback distances)
- undertake further investigations to establish and provide for maintenance of the minimum, and required range, in groundwater levels.

## 8 Glossary

**Aquatic**—A word that describes anything to do with water.

**Annual volumetric limit**—the maximum volume of water that may be taken under a water entitlement, in a water year.

**Environmental flow objectives**—a flow objective for the protection of the health of natural ecosystems for the achievement of ecological outcomes.

**Groundwater**—subartesian water and artesian water as defined under Schedule 4 of the *Water Act 2000*.

**Interim water allocation**—An authority to take water managed under an interim resource operations licence or a resource operations licence that represents a volumetric share of water, and any conditions attaching to the authority.

**Interim resource operations licence**—A licence granted under Section 175 of the Water Act.

**Mean annual discharge**—The average volume of water that is discharged at a location. It is found by summing the yearly volumes of water discharged over a series of years and dividing the total by the number of years in the series.

**Mean annual flow**—the average volume of water that is discharged at a location. It is found by summing the yearly volumes of water discharged over a series of years and dividing the total by the number of years in the series.

**Median annual flow**—the middle value in a series of values that describe the yearly volume of water discharged at a location, when the values are ranked in order of size.

[For example: The median annual flow for the following sequence is 200 000 ML—500 000 ML, 300 000 ML, 200 000 ML, 150 000 ML and 100 000 ML. The mean annual flow is 250 000 ML.]

**Non-point source**—the discharge doesn't come from one identifiable source. For example, run-off from agricultural and urban sources does not usually enter a waterway at one point, but enters at a number of points.

**Refugia**—the habitat required by a species during a time of stress, for example, drought.

**Resource operations licence**—A licence granted under Chapter 2, Part 4, Division 3 of the Water Act.

**Resource operations plan**—a plan approved under Section 103 (2) of the Water Act. [Note: A resource operations plan implements water resource plan strategies and, among other things, guides the release of unallocated water and the day-to-day management of streamflows and water infrastructure for consistency with the water resource plan.]

**Supplemented water**—Water supplied under an interim resource operations licence, resource operations licence or other authority to operate water infrastructure.

**Unallocated water**—water that can be made available for future consumptive use for urban, rural or industrial uses without compromising the environment or the security of supply to existing water users.

**Unsupplemented water**—water, occurring in its natural state, that is, not supplemented by releases from infrastructure.

**Water allocation**—An authority granted under Section 121 or 122 of the Water Act to take water.

**Water licence**—a licence granted under Chapter 2, Part 6, Division 2 of the Water Act.

**Water resource plan**—a plan approved under Section 50 (2) of the Water Act. [Note: A plan to allocate and sustainably manage water in a defined part of Queensland.]

**Waterhole**—a part of a watercourse that contains water after the watercourse ceases to flow, other than a part of a watercourse that is within the storage area of a dam on the watercourse.

## Appendix A - Public Notice

**Department of Environment and Resource Management**

### Public Notice

**Availability of Draft Water Resource (Fitzroy Basin) Plan 2010**  
*Water Act 2000 Section 49*

**1. Purpose**  
 Notice is given under section 49 of the *Water Act 2000* that the Minister for Natural Resources, Mines and Energy and Minister for Trade has prepared a Draft Water Resource (Fitzroy Basin) Plan 2010 (draft plan). The draft plan has been prepared to replace the expiring Water Resource (Fitzroy Basin) Plan 1999.

**2. Proposed plan area**  
 The proposed plan area for the draft plan is identified in the map shown in this notice which is indicative only. The proposed plan area and more details of the location of the area boundaries are held in digital electronic form by the Department of Environment and Resource Management (the department), and may be inspected at the department's offices at 209 Bolsover St, Rockhampton.

**3. Inspection of draft plan**  
 Copies of the draft plan can be inspected at or obtained by contacting the department using the details specified in clause 5b of this notice. The draft plan may also be viewed or downloaded from the internet at <[www.derm.qld.gov.au/wrp/fitzroy](http://www.derm.qld.gov.au/wrp/fitzroy)>.

**4. Public information sessions**  
 The department will be holding public information sessions to provide further details on the draft plan. The dates and times for the information sessions are:

Location	Date	Time	Venue
Rockhampton	17 January 2010	09.00 am – 12.00 pm	Department of Employment, Economic Development and Innovation Conference Centre, corner Yeppoon Road and Bruce Highway, North Rockhampton
Biluela	18 January 2010	09.00 am – 12.00 pm	Department of Employment, Economic Development and Innovation Research Station, Conference Room, 86-102 State Farm Road
Theodore	19 January 2010	14.30 pm – 17.00 pm	Theodore Hotel, The Boulevard
Rolliston	19 January 2010	13.00pm – 16.00 pm	Rolliston Community Hall, Planet Street
Emerald	20 January 2010	09.00 am – 12.30 pm	Department of Environment and Resource Management Conference Room, 99 Hospital Road
Clarke Creek	21 January 2010	09.00 am – 12.00 pm	Clarke Creek Community Hall

Please contact the department on 1800 822 000 to register your interest for a session.

**5. Submissions**  
 Submissions may be made about the draft plan and the contents of the overview report. Anyone may make a submission. Submissions must:

- be in writing and signed by each person who made the submission;
- state the name and address of each person who made the submission;
- state the grounds of the submission and the facts and circumstances relied on in support of the grounds;
- be received on or before 5 pm 28 February 2010; and
- be received by the person stated in clause 5a of this notice.

Email and internet submissions will also be accepted.

*Submissions should identify information that is considered confidential. The department will endeavour to maintain the confidentiality of information that is identified in this way, however submissions are subject to the Right to Information Act 2009 and information may be required to be released upon requests made under this Act. Furthermore, other legal obligations, such as the processes of the courts or natural justice may also override confidentiality.*

**6. Enquiries**

(a) Submissions on the draft plan must be addressed to:

**Postal address:**  
 Attn: [redacted]  
 Water Services (Fitzroy WRP)  
 Department of Environment and Resource Management  
 Rockhampton State Gov. Bld. 1.3  
 PO Box 1762  
 Rockhampton Qld 4700

**Street address:**  
 209 Bolsover Street  
 Rockhampton Qld 4700

**By email:**  
[wrpfitzroy@derm.qld.gov.au](mailto:wrpfitzroy@derm.qld.gov.au)

**By facsimile:** (07) 4938 4011

**By internet:**  
 <[www.derm.qld.gov.au/wrp/fitzroy](http://www.derm.qld.gov.au/wrp/fitzroy)>

(b) Further enquiries should be directed to [redacted] Department of Environment and Resource Management at [redacted]. Alternatively, information can be viewed or downloaded via the internet at <[www.derm.qld.gov.au/wrp/fitzroy](http://www.derm.qld.gov.au/wrp/fitzroy)>.

Dated this 14th day of December 2010

**Stephen Robertson**  
 Minister for Natural Resources, Mines and Energy  
 and Minister for Trade

# Appendix B - Moratorium Notice

## Department of Environment and Resource Management

### Moratorium Notice

#### Fitzroy Basin

#### Water Act 2000 (Qld) Section 26

1. This is a Moratorium Notice (the Notice) under section 26 of the Water Act 2000 (Qld) (the Act) for the Fitzroy Basin (the Area) as shown in the indicative map below.  
 Note: The map shown in this notice is indicative only. The map of the area and more details of the location of Area boundaries are held in digital electronic form by the Department of Environment and Resource Management (the department) and may be inspected at the department's Rockhampton office at 206 Bolsover Street.
2. The Notice has effect on and from 14 December 2010.
3. The following moratorium notices in the Fitzroy Basin cease to have effect on and from the day this notice has effect:
  - (a) the moratorium notice for the Callide Subcatchment which had effect from 15 December 2006; and
  - (b) the moratorium notice for the Isaac River and Connors River catchment which had effect from 15 December 2006.
4. This Notice applies to:
  - (a) the following water within the Area:
    - i. underground water in the Callide, Fitzroy, Highlands and Great Artesian Basin declared subartesian areas that is not dealt with in the Water Resource (Great Artesian Basin) Plan 2006;
    - ii. water in a watercourse, lake or spring.
  - (b) all applications for or about a water licence to take or interfere with the water mentioned in clause 4(a)(i) if granting the application would have one or more of the following effects on the water:
    - i. increase the amount of water that may be taken;
    - ii. increase or change the interference with the water.
  - (c) all applications for or about a water licence to take water from a watercourse, lake or spring in the part of the Area identified in the map below as the Lower Fitzroy Area if granting the application would have the effect of increasing the amount of water that may be taken;
  - (d) all applications for or about a water licence to interfere with the flow of water in a watercourse, lake or spring by impoundment if granting the licence would have the effect of increasing or changing the interference with the water;
  - (e) works to take underground water in the parts of the Dun River catchment and the Isaac and Connors Rivers catchment, as shown on the map below, that are outside the declared subartesian areas mentioned in 4(a)(i) and would increase the amount of underground water being taken or that could be taken.  
 Note: The Lower Fitzroy Area is that part of the Area from which water flows into the reach of the Fitzroy River downstream of the Fitzroy River Barrage.
5. Applications stated in clause 4 of this notice received:
  - (a) before the day the Notice has effect, will not be dealt with;
  - (b) on or after the day the Notice has effect, will not be accepted.
6. Clause 5 of the Notice does not apply:
  - (a) if the application relates to water mentioned in clause 4(a)(i) and is an application:
    - i) to reinstate or replace a water licence under section 221 or 229 of the Act;
    - ii) for taking water for stock purposes or domestic purposes;
    - iii) that does not relate to water in the Callide Valley alluvium and is an application:
      - (A) for a water licence to take water for a significant project declared under section 26 of the State Development and Public Works Organisation Act 1971;
      - (B) for taking water for mine dewatering purposes;
      - (C) for a water licence to take water for town water supply purposes;
      - (D) for construction, operation or maintenance of public utilities;
    - iv) if a development permit authorising construction of works to take the water to which the application relates has been given and is current.
  - (b) if the application relates to taking water mentioned in clause 4(a)(ii), is an application for taking water in the Lower Fitzroy Area and is an application:
    - i) to reinstate or replace a water licence under section 221 or 229 of the Act;
    - ii) for taking water for stock purposes or domestic purposes;
    - iii) for a water licence to take water for town water supply purposes;
    - iv) for a water licence to take water for a significant project declared under section 26 of the State Development and Public Works Organisation Act 1971.
  - (c) if the application relates to interfering with water mentioned in clause 4(a)(i) by impoundment and is an application:
    - i) for interfering with water for stock purposes or domestic purposes;
    - ii) for a water licence to interfere with water for town water supply purposes;
    - iii) for a water licence to interfere with water for a significant project declared under section 26 of the State Development and Public Works Organisation Act 1971;
    - iv) to meet the requirements of an environmental authority issued under the Environmental Protection Act 1994;
    - v) to access water under an entitlement granted from a process for the release of unallocated water.
7. While the Notice has effect:
  - (a) new works must not be physically started;
  - (b) completed works in existence must not be raised, enlarged, deepened or changed;
  - (c) works that have been started must be completed by 15 June 2011;
  - (d) a person that is completing the works that have been started must give the chief executive notice about the works by 5:00 pm on 12 February 2011;
  - (e) construction of works must stop if notice has not been given under paragraph (d).  
 Note: Notice of started works should be given in writing to the chief executive at the department's Rockhampton office, 209 Bolsover Street, Rockhampton.
8. Works mentioned in clause 7 of the Notice are not started unless:
  - (a) construction of the works has physically started, or if construction has not physically started, a contract had been entered into to start the construction and construction is started within 60 days after the day the Notice is published;
  - (b) an independently verifiable construction program exists for progressive construction towards completion of the works;
  - (c) detailed design plans exist showing, among other things, the extent of the works;
  - (d) if a development permit is required for the works or for other development associated with the works - the development permit has been given.
9. Clause 7 of this notice does not apply to works:
  - (a) for taking water for stock purposes or domestic purposes;
  - (b) for taking or interfering with water for town water supply;
  - (c) for taking or interfering with water for a significant project declared under section 26 of the State Development and Public Works Organisation Act 1971;
  - (d) for which a development permit authorising the works as operational works for taking or interfering with water has been granted;
  - (e) for construction, operation or maintenance of public utilities;
  - (f) for taking water for the purpose of mine dewatering; or
  - (g) to replace works in existence and operable on the day this Notice has effect.
10. A person must not start the construction of works, or continue to construct works, in contravention of clause 7 of this notice.  
 Note: A contravention of clause 7 of the Notice is an offence under section 26(6) of the Act and renders a person liable to a maximum penalty of 1665 penalty units.

 Minister for Natural Resources, Mines and Energy  
 and Minister for Trade

# Environmental Flow Assessment Program

---

## What are environmental flows?

Environmental flows are critical to the health of waterways and rivers. They refer to the amount of water required to sustain healthy aquatic ecosystems. This includes the:

- flow regime
- frequency
- timing
- magnitude
- duration.

Environmental flows support the diversity of species and processes in aquatic ecosystems and maintain habitat conditions and river channel shape.

Under Queensland's water resource planning process, environmental flows are defined as the overall patterns of flow that remain after a set of rules have been applied to meet the outcomes of a Water Resource Plan (WRP), rather than a specific amount of water that is reserved for a river.

## What is the Environmental Flow Assessment Program?

The Department of Environment and Resource Management (DERM) is responsible for overseeing the Environmental Flow Assessment Program (EFAP) in Queensland, which assesses the rules and strategies specified in WRPs and their effectiveness in achieving the intended ecological and community outcomes.

WRPs are implemented through a Resource Operations Plan (ROP).

## What is an ecological asset?

An ecological asset is a highly valued component of the environment.

For the purposes of assessing a WRP, an ecological asset is defined as a species, biological function or place of value for which water is critical.

The term critical means water is necessary to maintain the biological integrity of the asset.

Ecological assets should naturally occur in a plan area and be linked to the ecological outcomes of the plan.

## How are ecological assets used?

Ecological assets are used as indicators of an ecosystem.

As it is not possible to monitor all parts of an ecosystem to build knowledge of critical water requirements, the intention is to select a range of assets that adequately represent the ecological outcomes for a plan area, and are representative of the ecosystem as a whole.

Together, the ecological assets selected represent the ecosystem and enable a manageable method for monitoring whole ecosystem outcomes of water management.

## What is the purpose of the program?

The purpose of EFAP is to:

- confirm the critical water requirements of ecological assets and build scientific knowledge to underpin water management decisions
- determine if current flow management strategies are providing critical water requirements
- determine the risk to ecological assets and evaluate if ecological outcomes in a WRP are likely to be met under current flow management strategies.

## What is the link between the ecological asset and water management?

There may be many links between the ecological asset and water; however, the links of interest are those critical to the protection of the asset.

For example, the survival of a particular fish species may be critically dependent on flow conditions, e.g. rising water level/depth and timing of the rise to allow for spawning (egg laying). In the absence of these flows, adult fish may survive but there will be no spawning, and the long-term viability of the ecological asset will not be guaranteed.

As another example, Murray River red gums need regular flooding to maintain established trees, ensure seed production and seedling development.

Timing, duration and frequency of inundation provide the critical conditions necessary for the long-term survival of the ecological component (asset) that we value (river red gum).

## How will we assess if the plan is working ecologically?

The scope of the ecological performance monitoring is to:

- increase scientific knowledge about the critical water requirements of the ecological assets
- determine whether water management, through the strategies in the WRP and ROP, are providing the critical conditions in terms of water for long-term sustainable populations of ecological assets.

Based on this knowledge, the risk to the assets of interest can be predicted over the long term and used to indicate whether the ecological outcomes in the WRP area are adequately provided for.

Activities undertaken each year in the EFAP build toward an assessment of the ecological effectiveness of a WRP when it is reviewed every 10 years.

## How is ecological condition assessed?

Ambient monitoring undertaken by DERM will compliment the EFAP. As such, the development of DERM's Stream and Estuary Assessment Program will ensure not only that the condition and trend of ecosystem condition is known but also that potential causes of ecosystem condition decline can be identified.

The EFAP will enable the effect of flow management on this condition to be partitioned from other effects.

## When will the results of EFAP be available?

The results of knowledge-improvement projects under the assessment program to confirm critical links of the asset/s to flow will be reported annually in the minister's annual report for a WRP. This report is available via the DERM website <[www.derm.qld.gov.au](http://www.derm.qld.gov.au)>.

This report also outlines the effectiveness of a plan in achieving its outcomes. A full assessment of a plan's effectiveness will be made as part of the review of a WRP, when triggered, or routinely at year 10 of a plan's life.

## What will happen in my catchment area?

This depends on the ecological assets identified in a catchment and their critical water requirements.

Once ecological assets for a catchment have been identified, a preliminary risk assessment will be undertaken to prioritise those areas and assets where monitoring and knowledge improvement activities should be focussed.

Community consultation of asset selection and prioritisation may then occur. The extent of monitoring efforts will reflect the level of risk in the catchment, thus monitoring is likely to be more intensive in some catchments than others.

## More information

More information can be found on the DERM website <[www.derm.qld.gov.au](http://www.derm.qld.gov.au)> or by emailing <[water.monitoring@derm.qld.gov.au](mailto:water.monitoring@derm.qld.gov.au)>.

# business case

*// the complete picture on river health*

# The Fitzroy Partnership for River Health is a collaborative new approach to sharing information about local waterways that will deliver:

- More comprehensive and reliable water quality information.
- An engaged community that is more aware of waterway health issues.
- Recognition and improved credibility for monitoring partners.

## What makes the Fitzroy Basin special?

The Fitzroy Basin is about twice the size of the state of Tasmania. It is a large and diverse region that includes within its borders around 20% of the state's beef cattle, most of Queensland's coal mines and coal seam gas production, unique landscapes and a rich abundance of flora and fauna. An extensive

20,000km network of waterways snake across the basin's terrain. Five major tributaries flow across the expansive delta and then meet to form the mighty Fitzroy River which drains to Keppel Bay, forming part of the world heritage listed Great Barrier Reef. It is also home to internationally significant wetlands and waterways containing the greatest diversity of freshwater fish in Australia.

## Our Challenge

Maintaining healthy waterways as well as economic prosperity is a critical challenge for the Fitzroy Basin. We need to find the right balance to ensure our communities and environment will flourish, and we can capitalise on economic opportunities without degrading our natural resources. Public scrutiny of environmental performance and regulatory measures are increasing across all sectors. This is demonstrated by the fact that over 26 independent waterway monitoring programs currently operate across the basin.

This uncoordinated approach means that:

- Opportunities to value-add and share information are being missed.
- People concerned about waterway health do not have a clear entry point for finding relevant local information.
- Decision-makers must wade through a large amount of monitoring data to inform their management, regulatory and policy choices.

Investment in integration, interpretation and communication of waterway health information will ensure that we as a community have the complete picture, to help us effectively manage waterway health for the future.

# Why Participate?

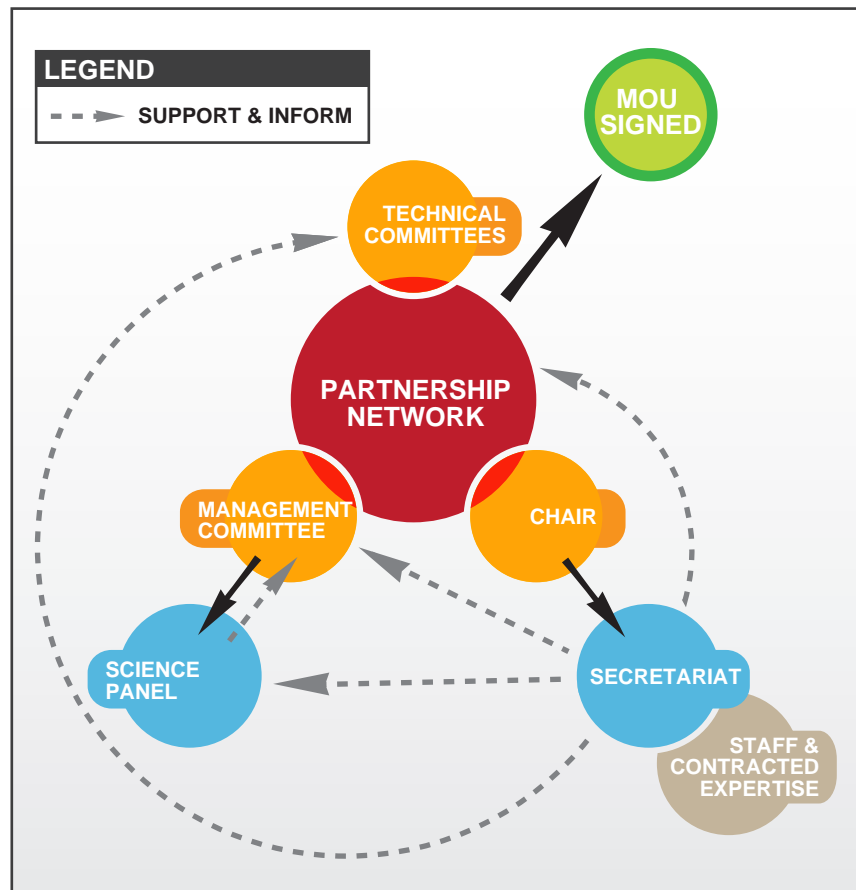

- Demonstrate your commitment to a community informed by a coordinated approach that delivers accessible, reliable and trustworthy waterway health information.
- Meet far field monitoring requirements if you are an organisation with a relevant environmental authority – the Department of Environment and Resource Management has provided assurance that participation in this program will satisfy their requirements.
- Information and knowledge generated will support water management planning activities by councils and be recognised and trusted by ratepayers.
- Achieve cost efficiencies, access to better information and improved credibility within the general public.
- Establish new networks, grow your knowledge base, and gain a competitive decision-making edge.
- Confirm your commitment to better informed policy, planning and management decisions.

## Our Proposal

Over the last year representatives from 22 organisations have worked together to lay the foundations of a monitoring partnership. The Fitzroy Partnership for River Health is a collaborative approach where data from current monitoring programs will be compiled. Looking at the combined data will allow us to provide the community with an assessment of waterway health across the basin.

With your support, the process could include:

- Adding to existing monitoring efforts to fill knowledge gaps.
- Development of waterway health methodologies and indices to assess data.
- Reporting waterway health by focusing on the Fitzroy Basin's 10 major catchments, plus estuaries and marine waters (see map).
- Interpreting and presenting scientific information in a simplified and understandable format for the general public.
- Creating compelling and interactive products in print and online, as well as media and events to communicate reporting results.

The partnership will develop a waterway health report card for the 2010-11 year that will be underpinned by several increasingly complex layers of information designed to demonstrate transparency and enable technical interrogation. Reporting and communication products will be made available to partners in June 2012. This will be followed by a

public launch in September 2012, which will provide recognition and exposure for organisations involved in the partnership as well as raise awareness of the report among the general public. In addition, the compilation of water quality monitoring information will be available for ongoing refinement of water quality guidelines for the Fitzroy Basin.

Purpose	Cost
Data Management and Assessment	\$479,772
Reporting and Communications	\$126,418
Governance and Administration	\$275,905
Sub-total	\$882,095
Additional Monitoring	\$315,000
<b>TOTAL</b>	<b>\$1,197,095</b>

## Our Resourcing Requirements

Investment is required to support these resourcing requirements. An annual membership fee of \$10,000 will apply to all signatory parties of the MOU and includes a seat at the Partnership Network and the Gold level of recognition and rights.

Funds will be requested in addition to the annual membership fee from particular parties including the Queensland Government, Regional Councils, Australian Government, holders of an Environmental Authority with water conditions, bulk water suppliers, Gladstone Ports Corporation and CQ University. In-kind support is also required in the form of waterway health monitoring data.

In appreciation of their commitment organisations investing \$50,000 or more will secure a Platinum level of recognition and rights.

## Further Information

Want to find out more? Several informative documents are available at: [www.riverhealth.org.au](http://www.riverhealth.org.au) including the MOU, Project Plan, Monitoring Plan Summary and Communications Plan.

To secure the sustainable development of Central Queensland, decisions must be based on sound science and an understanding of the capacity of our natural systems. The work of the partnership has significant potential to perform an important role in bringing together the extensive water quality monitoring being undertaken by various groups across the catchment and provide the community with integrated water quality information.

## Introduction

Water monitoring is undertaken by the Queensland Government for a variety of reasons, including the provision of information to government for policy and investment decision-making, to underpin natural resource management decisions by government and stakeholders, to assess impacts on the environment and to educate and inform stakeholders and the community generally.

Monitoring is also required to be conducted by persons under statutory approvals, and is additionally conducted by other organisations across Queensland, including local government, industry, regional natural resource management bodies and community groups. Many of these organisations collect valuable information on the condition of Queensland waters that complement Queensland Government monitoring.

The Monitoring and Sampling Manual 2009 provides the common techniques, methods and standards for sample collection, handling and data management for use by Queensland Government agencies, relevant persons and other organisations.

Where monitoring is required under legislation to be carried out under a protocol, the Monitoring and Sampling Manual 2009 is the principal document to decide the protocols. This manual is intended to be used by persons and organisations involved in the monitoring of the condition and trend of Queensland waters.

The Monitoring and Sampling Manual 2009 will facilitate consistency and increased scientific rigour of monitoring data available for interpretation by all stakeholders. It will allow them to assess the condition and trend of Queensland waters so that the aquatic environment can be managed for sustainable development and aquatic ecosystem health.

## Context

### 1.1 Edition identification

This second edition of the Monitoring and Sampling Manual 2009 (the manual) supersedes the first edition of that manual, and sampling manuals published by the former Environmental Protection Agency, Department of Primary Industries, and Department of Natural Resources and Water.

Each page has the publication title, version number and date of publication.

A copy can be downloaded from the Department of Environment and Resource Management's (the department's) website at <[www.derm.qld.gov.au](http://www.derm.qld.gov.au)>.

### 1.2 Purpose of the manual

The purpose of the manual is to provide the common techniques, methods and standards for sample collection, handling, quality assurance and control, custodianship and data management, for use by Queensland Government agencies, relevant persons and other organisations.

The manual is a part of an integrated monitoring framework to decide the priorities, indicator selection, data storage, data analysis and reporting, as shown in Figure 1 below.

Where monitoring is required under legislation to be done under a protocol, including the *Environmental Protection (Water) Policy 2009* (EPP (Water)) and the *Environmental Protection Regulation 2008*, the manual is the primary document to decide the protocols.

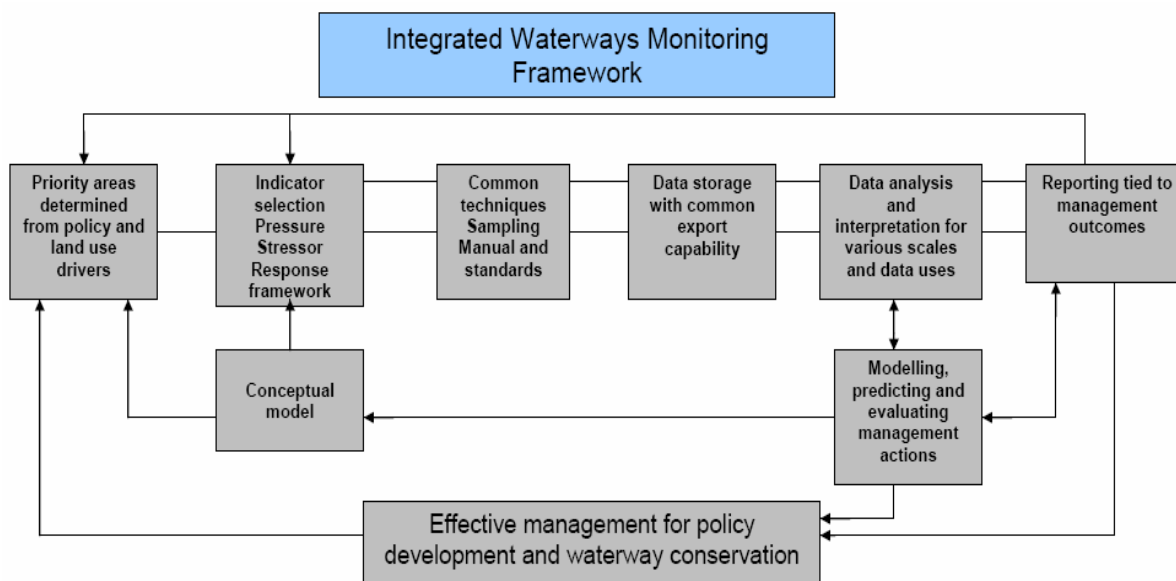

Figure 1.1 Integrated monitoring framework

### 1.3 Status of the manual

This manual is the updated version of the primary document originally listed in the, repealed, *Environmental Protection (Water) Policy 1997* for use in deciding 'protocols'. Accordingly, if there is any inconsistency between this manual and the other documents, this manual takes precedence to the extent of the inconsistency.

Some standards and other documents that have been used in preparing this manual will be revised from time to time. This could result in a procedure differing from that presented in the manual. The rules provided in Box 1.1 cater for such instances. In any situation where users of this manual use a revised document and/or adopt a protocol on the advice of an analyst, they should note the use of any revisions adopted and keep a record of the analyst's advice.

#### Box 1.1 When a standard is revised

If this manual is found to differ from a revision of any of the other documents listed in the EPP (Water), amended after the date of this manual, a user may decide that the updated version of the document is more appropriate than the manual for deciding a 'protocol', either generally or in particular circumstances. This manual should not be interpreted as being inconsistent with the other document provided that:

- the revision of the document is subsequent to the date of this manual
- the specific procedure in the document is revised in the updated document
- an analyst advises that use of the revision in deciding the 'protocol' will lead to a determination of a quality as good as or better than that derived from using the manual.

### 1.4 Intended users

This manual is intended to be used by:

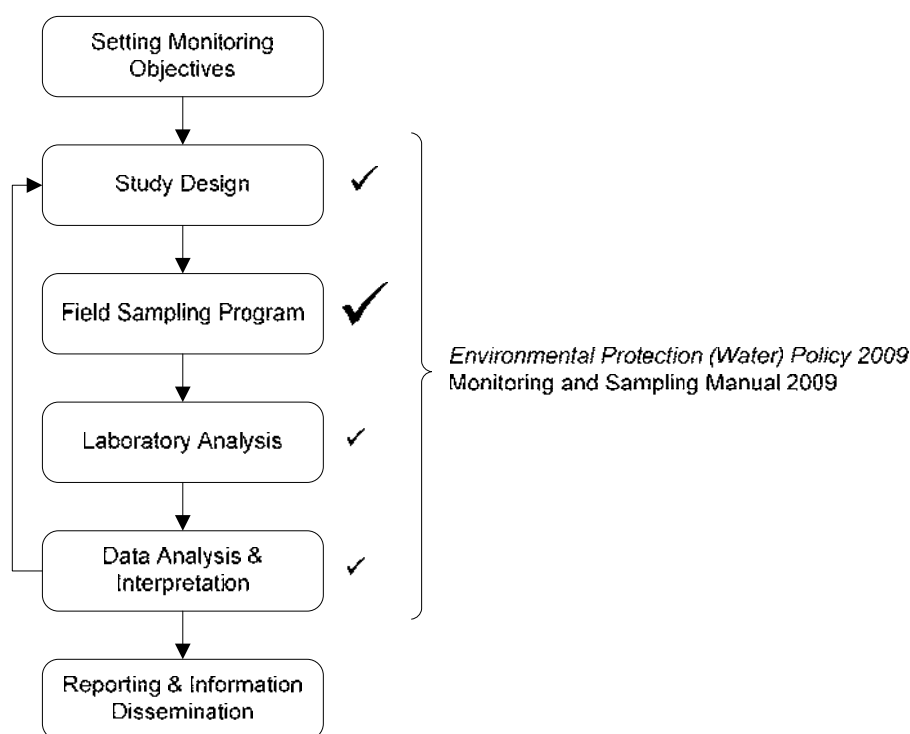

- those who hold instruments under the *Environmental Protection Act 1994* such as environmental authorities and development approvals (that comprise licences and approvals to carry out environmentally relevant activities) and Environmental Protection Orders
- employees and consultants of those who hold instruments under the *Environmental Protection Act 1994*
- those who analyse the samples collected for water quality determinations
- other persons and organisations involved in the monitoring of the condition and trend of Queensland waters.

### 1.5 Content of the manual

The manual's content has been prepared in consultation with other Australian environmental agencies and Queensland state and local government agencies. Australian and New Zealand and relevant international standards were considered during the preparation of this edition.

The manual is consistent with the nationally adopted framework presented in the Australian Guidelines for Water Quality Monitoring and Reporting (ANZECC/ARMCANZ 2000) and covers the sections of the framework indicated in Figure 1.2 below.

Australian Guidelines for Water Quality  
Monitoring and Reporting 2000

**Figure 1.2 Framework for a water quality monitoring program—Australian Guidelines for Water Quality Monitoring and Reporting (2000).**

This manual presents procedures for:

- sampling design
- sampling in the field:
  - making in situ tests and water quality measurements
  - taking samples for water quality assessments, including samples of wastewaters, environmental waters, sediments and biota
  - preserving and storing samples for water quality assessments, including samples of wastewaters, environmental waters, sediments and biota
  - security and transport of samples
- arranging laboratory analysis
- data analysis and interpretation.

## 1.6 Limitations

The manual cannot cover every set of circumstances encountered when determining a 'protocol' for sampling, and may not always provide sufficient or relevant directions. In situations where the user has little confidence that the samples might produce useful data, this should not stop them from being collected, particularly if there is no other opportunity to obtain the information they could provide.

## 1.7 Disclaimer

Where particular brand names of equipment are mentioned, this has been done for illustration purposes only. Other makes or brands providing equivalent function are equally applicable.

## PART A Sampling design overview

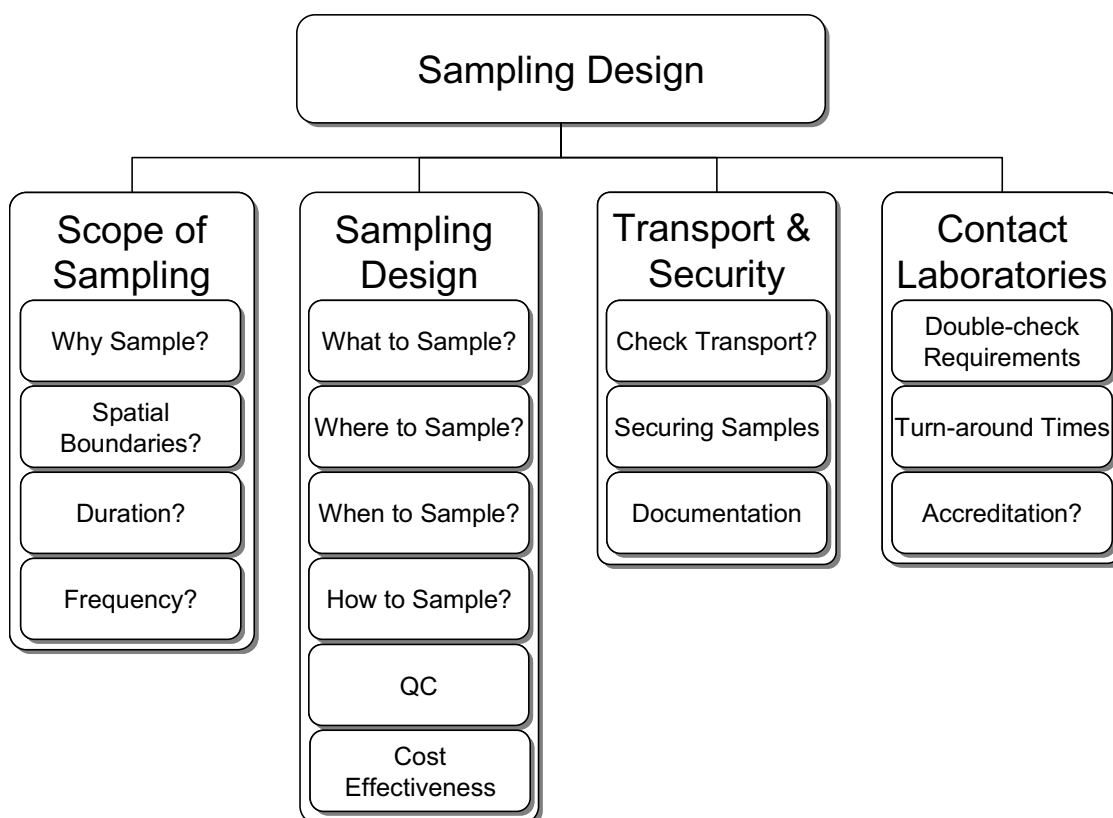

Figure 2.1 Essential components of a comprehensive sampling design

### 2.1 Sound sampling design is essential

Before any sampling is carried out, the aim of the sampling exercise and how the results will be used need to be established. For example, a single result might be compared with a written specification or benchmark (such as release limits in an environmental authority or development approval or with relevant guidelines). Alternatively, several results might be used in calculations, and if so, it needs to be understood how the calculated quantities will be used. Prior to collecting samples, the need to assess the circumstances and the kinds of inferences that could be drawn from the results of sample analyses should be determined. That information will help identify where and when sampling should take place, and the quality characteristics that need to be determined for those samples.

The essential features of a sampling strategy are to ensure that the material sampled is genuinely representative of the body of material from which it was collected, that in situ measurements are reliable, and that the integrity of materials sent for laboratory analysis has not been compromised by contamination, degradation, transformation or losses.

The basic intent of environmental analysis is that analysis is carried out with selected portions (i.e. samples) from the location of interest, and the quality of the source material is then inferred from that of the samples. If the source material quality is temporally and spatially consistent then this inference would be uncomplicated. However, such constancy is rarely, if ever, observed in the real world. For example, virtually all waters show both temporal and spatial variations in quality (see Box 2.1 and Box 2.2), and consequently the timing and choice of location/s for taking water samples must be chosen with great care. Other materials such as sediments and biota typically also show such variations.

When designing monitoring programs it is important to ensure that the sampling regime is representative of the system and parameter/s of interest. For example, where a water body is well mixed and a parameter of interest is evenly distributed in the water column a grab sample may be appropriate. However, it is important to consider that parameters of interest may not be equally distributed. In such circumstances it may be necessary to assess the variability of the parameter of interest within the water column **prior** to sampling.

Such an evaluation would aim to determine whether sampling at a particular point is representative of a homogenous unit of water at a given point in time. Where the extent of variation is not known, the variation might need to be established by a pilot sampling program designed for that purpose, or a comprehensive range of samples taken to enable variability to be determined along with the primary aim of the sampling exercise.

In circumstances where undertaking an assessment of variability is not practical or possible it is recommended that information from relevant peer reviewed literature on the likely variability is used to provide guidance on an appropriate sampling strategy.

A similar approach to dealing with variability is recommended when designing sampling programs involving the collection of other materials such as sediments and biota.

When deciding the number of samples to collect and the frequency of sampling required, ideally, sufficient samples and replicates would be collected to represent the full range of variability present in space and time. Sampling designs should ultimately be defined by program objectives that can include the required statistical power required for discriminating between hypotheses or be based on the levels of acceptable sampling variability. Sampling designs should also be guided by the 'where to sample' and 'when to sample' sections in this manual (Sections 2.3.3 and 2.3.4).

#### **Box 2.1 Variability of water quality over time**

If the environment to be sampled shows changes over time—for example, river systems within minutes or hours, or lakes within days or weeks—the temporal pattern of sampling is of great importance. The schedule for the sampling program should take account of the expected temporal resolution of changes in the environment. In programs for monitoring wastewater treatment effluents, sampling around the clock may be required to determine whether control variables have been met or exceeded. A single sample can only be a snapshot at a single point in time and may not reliably represent typical conditions for a system that varies over time.

If many samples are taken over a period of time, it is often appropriate to match the sampling rate to the expected pattern of variation in the environment.

When it is necessary to quantify a contaminant load, multiple sampling periods may be needed. For example:

- Time-proportional sampling: samples containing identical volumes are taken at constant time intervals.
- Discharge-proportional sampling: the time intervals are constant but the volume of each sample is proportional to the volume of discharge during the specific time interval.
- Quantity-proportional sampling (or flow-weighted sampling): the volume of each sample is constant but the temporal resolution of sampling is proportional to the discharge.
- Event-controlled sampling: depends on a trigger signal (e.g. a discharge threshold). For example, to detect peak concentrations during short-term changes of water quality, event-controlled samplers are useful.

Alternatively, passive samplers can be used to integrate variations in water quality over an extended period of time. For further information on the applicability and use of passive samplers see Appendix C2.

**Box 2.2 Variability of water quality in space**

It is important to understand how natural processes in environmental waters can affect water quality characteristics, and to be aware that water bodies are not homogeneous within a cross sectional area or depth profile.

Water bodies can be stratified (layered). This means the composition of the different layers is substantially different in respect of at least one characteristic. For example, in estuaries, water quality characteristics can vary because of ingress/egress of saline waters. Estuaries are commonly stratified when freshwater flow is much larger than tidal flow; the fresh flows seawards over the saline waters and a 'salt wedge' develops. Stratification could also result from temperature effects in waters with low current velocities. Such stratification is usually most pronounced in summer months when surface waters are much warmer than bottom waters. After separation, the water layers often develop markedly different chemistry. Such layers also tend to prevent mixing of discharged contaminants.

When sampling environmental waters (typically, when investigating a pollution incident), it could be important to remember that stratification might have occurred, and to take measurements at different depths to show whether this is so. The reverse process (de-stratification) can occur when the seasons change. The resulting inversion ('turnover') of the water can result in low oxygen water rising to the surface and causing adverse effects (such as odours from anaerobic decomposition at depth, and/or nutrient/metal enrichment). Other examples include the distribution of suspended solids within the water column from physical processes of re-suspension, deposition and flocculation. The concentration of suspended solids is dynamic in the water column and can fluctuate naturally according to flow conditions and water chemistry.

When the purpose of sampling is to assess compliance with a statutory provision such as a condition attached to an Environmental Authority or Development Approval, the sample should be taken to provide a reliable measure of the specific characteristic or parameter specified (e.g. the concentration of suspended solids at a defined sampling point). Where the statutory provision is not explicit, the sample should represent fairly the body of material from which it is taken during the period of the sampling.

Where the aim of the sampling is to measure compliance with conditions of an environmental authority or development approval, and the conditions include a statistical sampling regime, this should be followed so that the results can be of use. However, if there is reason to believe variability is a confounding factor, additional samples may be needed to check this out.

The *Environmental Protection Act 1994* and its subordinate legislation, including the Environmental Protection Regulation 1998 and the Environmental Protection (Water) Policy 2009, must be taken into account when deciding where and when to sample for compliance in a pollution investigation, checking compliance with an environmental authority or development approval, or undertaking a receiving environment monitoring program.

Reference should be made to the current conditions of any relevant licence or permits, particularly when confirming compliance. The conditions may include specific sampling locations, times of release and quality characteristics that will assist with designing the sampling strategy.

**2.2 Determining the scope of the sampling strategy****2.2.1 Defining the aims and objectives of sampling****2.2.1.1 Purpose of sampling**

Monitoring and assessment that involves sampling can be undertaken for a range of reasons. Some of the primary reasons covered by this manual include:

- investigating pollution incidents—sampling at a site where pollution has been reported can be challenging as you might not be aware of the constituent pollutants, or often the source of the release. In such cases, the aim of sampling should be to obtain evidence that will:
  - discover and prove the nature, the source, and the effects of the contaminants
  - be performed in such a way as to be legally admissible in court
- confirming compliance to licence conditions of an environmental authority or development approval—sampling of wastewater that is stored or released by the holder of an environmental authority or development approval or similar legal instrument is often performed routinely to confirm compliance with the imposed conditions of release. To test for compliance with the conditions, samples must be collected in a manner that will ensure valid analysis results for those particular contaminants
- undertaking a receiving environment monitoring program
- undertaking an environmental evaluation of an activity.

### 2.2.1.2 Specific sampling objectives

The objectives of the sampling program should be determined and documented. These should be as specific as possible. Common sampling objectives include:

- determining if one or more contaminants found in a waste or in the environment have originated from a singular or multiple source
- determining whether one or more contaminants in a release are in sufficient quantity to cause adverse environmental effects consistent with those observed at the time of the incident
- determining whether the contaminants in a waste release are having a measurable impact on the receiving environment water quality and whether environmental values are being affected
- determining whether the quality of waters have changed significantly, consistent with the definition of the term 'environmental harm' in the *Environmental Protection Act 1994*, and confirm whether the observed environmental change(s) occurred as a result of the release.

### 2.2.2 Define the spatial boundaries of sampling

The geographic boundaries of the sampling event should be based on the issue of concern and the ecosystem type rather than on convenience and/or budgets. For example, some important considerations would include:

- the likely spatial uniformity of the parameter(s) of interest
- the size of the area to be assessed.

### 2.2.3 Define the temporal scale of sampling

Temporal scale refers to the length of time over which a system is to be observed; that is, the appropriate period of time over which the samples are to be collected.

Different processes operate at different temporal scales, and the sampling designer should incorporate all the important time-related considerations into the design. For example, the movement of sediment in a river system occurs over tens of years at the catchment scale, whereas toxicant effects may occur over days (transient) or be continuous in nature. The temporal scale and, similarly, the frequency of sampling (see below) need to be suited to the temporal characteristics and occurrence of the contaminant.

## 2.2.4 Define the frequency of sampling

Consideration needs to be taken of the frequency of observations (sampling events) required to provide sufficient resolution of the issues of concern. Sampling may be required every hour, day, week, fortnight, month or possibly only once a year. The sampling designer needs to determine a frequency of sampling (level of resolution) that is sufficient to satisfy the requirements of the program objective, yet not sample too frequently and cost more than necessary.

## 2.3 Sampling design

### 2.3.1 Importance of understanding the system being sampled

The achievement of good sampling design can be assisted if the designer has some understanding of the ecosystem for which the sampling program is being designed. This understanding is best formalised in a conceptual model (or process model) of the system being examined. The model can be a simple box diagram that illustrates the components and linkages in the system, or a graphical representation of the system. Whatever model is used, it should present the factors that are perceived to be driving the changes in the system and the consequences of changes to these factors.

During the formulation of a model, several decisions must be made or the model will be too complex. For example:

- What are the major issues of concern (e.g. nutrients, metal loads, bioavailable metals)?
- What ecosystem (including subsystem type) should the model describe (e.g. freshwater, marine waters, estuarine waters, wetland, seagrass bed, mangroves)?
- Which state of flow should the model describe (e.g. base flow, flood event)?

Once formulated, the process model can be used to help define:

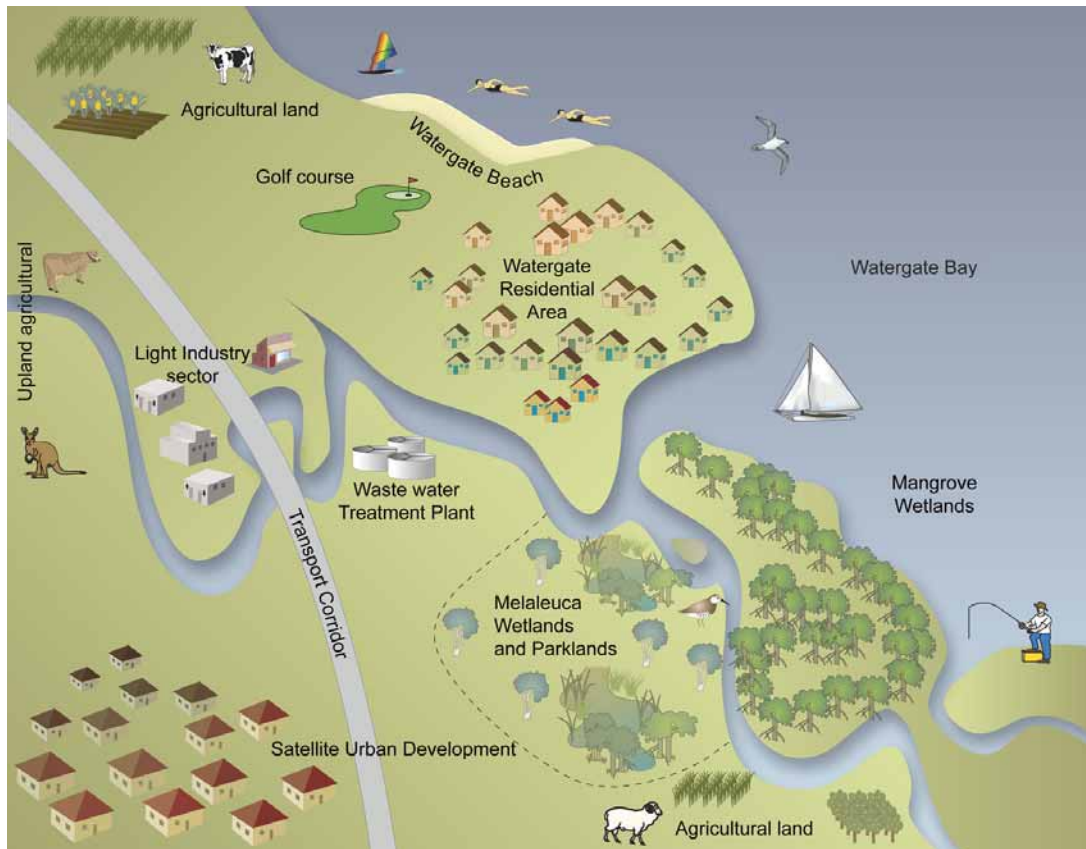

- important components of the system and the important linkages
- key processes
- cause–effect relationships
- important questions to be addressed
- spatial boundaries
- valid measurement parameters for the processes of concern; what to measure, and with what precision
- site selection
- time and seasonal considerations.

Examples of graphical conceptual models that may assist sampling design are at Figures 2.2, 2.3 and 2.4.

The importance of having an understanding of the ecosystem for which the sampling program is being designed is demonstrated by the complexity of nutrient cycling processes in waterways.

Plants use light as a source of energy for everyday growth and repair. They also require elements such as carbon (which they derive from carbon dioxide in the atmosphere) and the nutrients nitrogen (N) and phosphorus (P). Nutrients stimulate the growth of aquatic plants and are required to maintain the productivity of ecosystems. However, the growth of aquatic plants can be limited, despite there being sufficient light available, when nutrients are present only at minimal concentrations. Nutrients can become an environmental problem when they occur at

excessive concentrations. Negative effects of higher-than-normal nutrient concentrations include the eutrophication of waterways.

**Figure 2.2 Conceptual diagram of a coastal system including anthropogenic activities, inputs to waterways and areas of value**

Typical direct effects of eutrophication include increased frequency of algal blooms (including toxic algae) and hypoxia. Increased production of aquatic plants and algae may temporarily increase oxygen production within a water body, but when these decompose, this may cause a depletion of dissolved oxygen (DO). Low DO levels can lead to fish kills and the death of other aquatic fauna. Other effects of eutrophication may include increased turbidity and changes in community composition.

The nutrients N and P occur naturally in Australian surface water systems. They often occur in both particulate (i.e. organic and sediment-bound) and dissolved forms. The movement of nutrients from land may originate from both diffuse and point sources. Pathways for diffuse sources include riparian litter fall, soil erosion and sediment transport (see Figures 2.3 and 2.4). Fertilisers may be a source of N and P in agriculturally dominated catchments. The concentration and types of particulate and dissolved forms of N and P in waterways can indicate potential stresses from land uses and land management practices in the catchment.

An understanding of the relationship between flow and nutrient concentrations, coupled with N and P cycling (and the transformation from one form to another), is crucial when interpreting concentrations and loads and subsequently making any type of assumption or conclusion (e.g. is the nutrient a new contribution to the cycle or a transformation of a previously deposited load?). Without this understanding, changes in N and P concentrations and/or loads may be more attributable to variable flow regimes and biological factors rather than any imposed management action.

Figure 2.3 Typical processes affecting nutrients within different parts of a catchment

Figure 2.4 Illustration depicting typical nutrient and sediment inputs into catchments

## 2.3.2 What to sample

What material is relevant to collect samples of, and what measurements should be taken?

When checking compliance, environmental authority or development approval conditions typically specify the contaminants and the permitted ranges of concentrations allowed in the release. However, in cases of suspected environmental pollution incidents, you might not know what pollutants are present. Furthermore, when sampling the receiving environment, there are a range of related indicators that may need to be measured across different media such as surface water, sediments or biota. This section provides guidance on determining which characteristics should be sampled.

When choosing indicators, it is important to know whether there are defined benchmarks such as water quality objectives, guidelines, limits or other standards relevant to your situation to compare with your measured data. Indicators may be chosen because they have such benchmarks and may best indicate water condition or potential environmental harm. If no defined benchmarks exist, it is essential that your sampling design includes appropriate reference or control sites so that you are able to make a comparison against something.

### 2.3.2.1 Sampling media

The aim of sampling is to estimate quality characteristics of one or more of the following:

- wastes released to a water body (or potentially released)
- the receiving environment via:
  - a permanent or temporary water body—usually surface waters, but occasionally groundwater
  - bottom sediments of a permanent or temporary water body
- specimens of animal or plant life thought to have been affected by a release or by a change in natural conditions.

### 2.3.2.2 Sampling waste streams

Environmental authority or development approval conditions typically specify the contaminants and the permitted ranges of concentrations allowed in the release. Additional characteristics may provide greater information about the potential environmental harm that might be caused, for example, although only biochemical oxygen demand (BOD) might be specified in the environmental authority or development approval, chemical oxygen demand (COD) and total organic carbon (TOC) often provide more information, and could be worth assessing. It may also be important to measure other characteristics due to a change in an operating condition or a specific incident.

The characteristics being measured should relate to the potential contaminants used and/or generated in the process that produces the waste stream, in addition to their potential effects on the receiving environment.

In addition to measuring water quality characteristics, flow measurement of wastes/wastewater is often required for point source releases. This allows regulation and quantification of flow and loads of contaminants. Flow measurements of water bodies can be important for regulation as they can be used to assess initial mixing of point source discharges or as triggers to allow licensed discharges, particularly for event-based releases. Flow measurements of waterways may also be required for pollution incidents to assess or predict the extent of impact. Further information on flow measurement can be found in Appendix C3.

### 2.3.2.3 Sampling the receiving environment

Your assessment should take into account:

- potential sources of contamination
- likely contaminants
- type of waterway and flow rates; whether freshwater, estuarine or marine, and whether a flowing stream, lake, or ephemeral (in which case it may be wet or dry, or evaporating and concentrating contaminants at the time of sampling)
- licensed releases into the waters
- potential sources of releases
- recent weather such as heavy rain, showers or drought conditions
- historical occurrences of similar incidents.

## 2.3.3 Where to sample

### 2.3.3.1 Where should samples be collected and measurements taken?

Many environmental authorities have conditions which specify where samples are to be taken. Some have more than one sample point (two or more outlets, or an intake as well as an outlet). Where no sampling location is specified, you should take a sample from a site you judge to be representative of the release material (and the receiving waters, where relevant).

In more populated areas identification of a particular location can be assisted by a map of the area at a suitable scale (typically 1:25 000 or larger), or an aerial photograph showing individual buildings, preferably printed beforehand and taken with you. In more remote areas, use other points of reference, such as topographic features (hills, quarries, stream bends, etc.) or structures like fences or stone walls, and a global positioning system (GPS).

When investigating environmental pollution incidents, you should consider all possible sources of the pollutant, including licensed and unlicensed sources of release. You should aim to sample at the site of the pollution reported, at the point of any suspected contributing releases and also in an area upstream/distant from the suspected source.

It is important to identify with sufficient accuracy the location from which a sample has been collected to avoid raising a doubt about 'what the sample represents', particularly in cases where a location a few metres away might have given significantly different results. For example, in a river, was the location upstream or downstream of a tributary stream; or on the inside or outside of the bend? Or, where multiple discharge points exist, could it have been the one 'next to' the one claimed? This last instance could be significant when investigating complaints in situations where you do not know what other discharges may have occurred.

## 2.3.4 When to sample

### 2.3.4.1 Timing of sampling

The timing of the sampling should address the pre-defined objectives of the program. When there is a suspected environmental incident, it is prudent to sample as soon as possible after the incident has occurred.

Some conditions on environmental authorities specify that release is to take place only at certain times of the day (for example, on an outgoing tide) or under certain weather conditions. This should be considered in your sampling design where applicable.

For impact assessments, sampling before and after is important (but not always possible), preferably with multiple before and after reference sites. In situations where there is no 'before' information available at the impact location, data collected by sampling from reference sites may be indicative of conditions at the impact location prior to the incident. For example, a chemical spill may have contaminated the receiving environment, and caused impacts on local biota, but there are no pre-spill data available. However, concentrations of contaminants or macroinvertebrate population indices measured at unimpacted reference sites after a chemical spill can be indicative of what those parameters could have been at the incident location prior to the spill.

Water quality varies with stream flow conditions, so in considering the timing of sampling, it is important to establish whether sampling during baseflow or during flood event conditions (or both) is appropriate.

### 2.3.4.2 Sampling during baseflow and event conditions

As maximum and minimum values for water quality indicators may be reached either during high and or low flow events, it may be necessary to target either baseflow and or event conditions of rivers or streams. Fluctuations in water quality may also occur due to effluent discharge from a point source. Baseflow sampling is carried out when the flow is predominantly influenced by groundwater and has little overland flow component (i.e. no flow derived from runoff after rainfall). Baseflow sampling of streams should be undertaken with adequate lag time following an event. In general, a period of at least six weeks following a major flow event should be allowed to elapse to ensure samples are solely baseflow water and are not capturing the tail of an event. An 'event' is classified as any significant rise in water level caused by rainfall. Sampling regimes for event sampling may be targeted at obtaining results from either smaller more frequent events, or larger but less frequent events. Episodic events are known to transport large quantities of some contaminants though, in some circumstances significantly higher concentration peaks can occur in much smaller but frequent flood events (see example in Figure 2.5). In some cases, these smaller more frequent events may also have a greater contribution to total or annual contaminant loads. Sampling of a flood event can include a series of discrete 'grab' samples collected to represent the extent of the event. See Appendix C10 for more information on grab sampling procedures.

Figure 2.5 Example of contaminant fluctuations with stream flow

## 2.3.5 How to sample

### 2.3.5.1 How many samples should be collected?

Unless the material being sampled is known to be well mixed (well mixed water body or end-of-pipe discharge), it is unlikely for a single measure to be representative of the source body of material. Multiple measurements are needed to allow the calculation of a mean and confidence interval for the characteristic of interest, or to allow statistical testing for significant differences between locations or non-compliance with statutory provisions. This requires multiple readings for in situ measurements and multiple samples where laboratory analysis is involved. A minimum is three data points per site for basic statistical tests, but more may be required depending on the inherent variability in the measurement data. Just how many data points are needed may not be known until after chemical analysis of some samples. Accordingly, it is sometimes good practice to take additional samples and to store these for subsequent analysis if required. However, the requirements of maximum holding times for many contaminants may make this untenable.

### 2.3.5.2 Is grab sampling adequate or should composite samples be taken?

Most samples taken will be grab samples—taken by filling sample containers over a ‘short’ period (seconds or minutes). A single grab sample may be used where a hazardous situation has arisen or is suspected and the sample is taken to confirm the presence of the hazardous substance.

A single grab sample may also be used where the body of water being tested is well mixed and its quality can be adequately described by a single sample. However, in many situations, a single grab sample in isolation is of limited use because it takes no account of variations in quality with time or space (see Box 2.1 and Box 2.2). In such a situation, the taking of a composite sample is a useful strategy. A composite sample may be temporal by combining contributions of material collected over a longer period (minutes, hours or days). Alternatively, a composite sample may be spatial, for example, comprising a series of equal contributions of material taken along a transect (e.g. across a channel). This gives a spatially ‘more representative’ sample than a single grab sample at a single point. An example of the advantage of using composite sampling occurs in measuring concentrations of total nitrogen from a sewage treatment plant for the purpose of estimating loads. A single weekly grab sample will not capture the variations across a day or week. A suitable alternative would be to take a 24-hour composite sample.

Notes:

Composite sampling will not provide information on the maximum concentration reached (i.e. spikes in concentrations) which is often relevant when dealing with toxicants.

The use of automatic samplers to prepare composite samples over a period of time could be problematic due to delays in delivering samples to the laboratory for analysis. Under some circumstances this might not be significant, but you should check with the analyst before sampling with such equipment.

## 2.3.6 Quality control in sampling

Quality control is an important part of any sampling exercise. The purpose of a quality control scheme is to check whether bias, sample contamination, or analyte loss could affect the results, and so invalidate the process.

Suitable techniques include:

- reference sites: comparable (but unimpacted) locations where samples are taken for comparison with others (for example, upstream of a discharge point, or a tributary other

than the one of interest). Unless the condition of the reference site/s is known, and because of variability, it is often wise not to rely on a single reference site

- control samples, including:
  - field spikes—an uncontaminated sample of the media (e.g. water) contained and preserved in an identical fashion to the field samples is spiked with contaminants of interest and accompanies the field samples during the sampling. Analysis of the spiked sample quantifies analyte loss (if any) through comparison with the spiked concentration
  - field, transport and container blanks—uncontaminated samples of the media (e.g. water) contained, handled (for example filtered) and preserved in an identical fashion to the field samples are analysed and measures of introduced contaminant (if any) are used to quantify and trace contamination problems associated with the sampling methods and materials.

These techniques are discussed in AS/NZS 5667.1:1998.

It is recommended that you discuss this aspect with the analyst during planning of a sampling exercise, particularly if the results are liable to be used in making decisions which could have significant health related, financial or legal implications.

### **2.3.7 Cost effectiveness**

It is preferable for the cost of sampling programs to be as small as possible while still meeting the stated objectives of the monitoring study. Cost-effectiveness considerations involve trade-offs between loss of statistical 'power' (i.e. the capacity of a program to discriminate between various hypotheses) and the cost of data acquisition. Costs of data acquisition taken into account for cost effectiveness include:

- the number of sampling stations, sampling occasions and replicates
- the cost of collecting samples (staff, transport, consumables)
- the cost of analysis
- the cost of data handling and interpretation (cost of reporting).

Cost-savings can result from collaborative monitoring, for example, when local councils pool resources with other water managers to comprehensively monitor a particular water body.

## **2.4 Transport and security of samples**

Samples collected in areas remote from the laboratory might need to be freighted by private companies—road or air transport—if the sampler cannot deliver them personally. The samples need to be delivered within the maximum holding times.

## **2.5 Contact laboratories**

When possible, contact the appropriate laboratories before going to the field to ensure that analysis can be performed before expiry of the maximum holding times.

You should inform the laboratory of details concerning the samples you will be sending. One way is to send a completed copy of a form such as the Notice of Samples Expected shown in Appendix C1. Send this by mail when the sampling is planned some days ahead, or by facsimile or email if urgent. If this is impracticable, try to contact the analyst by telephone to give details of the samples.

You should also try to give the laboratory any information you can about the sample source, likely range of concentrations and purpose for which the results are to be used. This will help the analyst choose a suitable analytical method with appropriate 'limit of reporting' (LOR). In some cases the LOR can be improved if the analyst knows these details beforehand.

If sampling from areas affected by a chemical spill, try to advise the laboratory to expect high concentrations in the samples. Providing the laboratory with such information may help avoid results such as 'out-of-range' concentrations, and subsequent delays while your samples are diluted and re-analysed.

## 2.6 Sampling schedule

Once the sampling design has been finalised a sampling schedule should be prepared that includes such information as:

- where and when the samples are to be collected
- source of each sample—whether from wastes, waters or sediments
- the nature of the material to be sampled
- the quality characteristics being sampled
- the sampling containers (and associated paraphernalia) needed
- preservatives needed
- the maximum holding time for each sample.

A blank copy of a sampling schedule form is located at Appendix C1. (Details of sample containers, preservatives and holding times are given in Appendix C8).

## 2.7 Useful source documents for sampling design

Source documents for sampling design are shown in Table 2.1.

**Table 2.1 A selection of relevant Australian and New Zealand standards related to water and sediment sampling**

## PART B Sampling physico-chemical indicators of water quality and environmental health

### 3.1 Sampling in the field

This section details the equipment and materials to be used in sampling. Appendix C1 contains a checklist of equipment and materials. You can copy this checklist for each sampling trip, and modify it as needed.

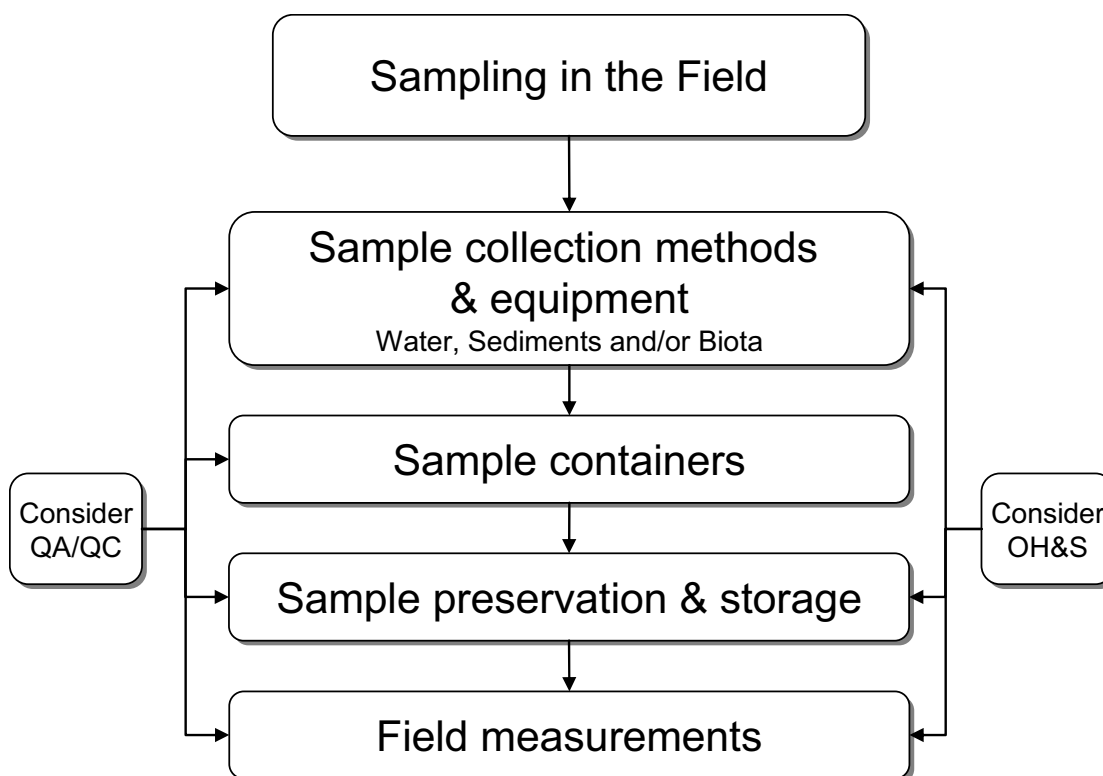

Figure 3.1 Necessary materials and equipment considerations for sampling in the field

#### 3.1.1 Using intermediate containers and sampling rods

It is always best to collect samples directly into the appropriate bottle or jar. However, it is sometimes necessary to use an intermediate container in order to collect samples, using buckets, beakers, pumps, filters, syringes, sediment grabs, trowels and/or sampling rods.

In using intermediate containers, contamination of the intermediate containers from previous samples becomes a risk. Contamination of the sample can occur by leaching of previous substances from the walls of the intermediate container, or loss of analyte by adsorption on to the walls of that container.

For samples containing substances in 'trace' concentrations, typically in the microgram-per-litre ( $\mu\text{g/L}$ ) range (such as trace metals and pesticides), use of an intermediate container should be avoided if possible. Sometimes the use of 'intermediate containers' such as syringes and filtering equipment or components of automatic samplers is unavoidable, and so precautions to reduce the risk of contamination are critical.

If samples need to be collected using intermediate containers, it is important that intermediate containers be pre-washed (for example syringes and filters) or flushed (for example in the case of automatic sampler lines) with existing site water before being used for the final collection of samples. The use of field blanks (see section 2.3.6) can identify sample contamination issues.

A sampling pole with a large clamp (or other suitable device) to hold the sampling containers can be used to give greater reach when collecting samples (see Figure 3.2). If the rod becomes contaminated, wash it promptly, making sure the washings cannot contaminate any samples or any material about to be sampled (for example by disposing of washings downstream of the sampling site).

Figure 3.2 Sampling pole and sample bottle

### 3.1.2 Automatic samplers

In some circumstances it may be preferable to use an automated sampling device to collect samples (Figure 3.3). When sampling flood waters it is often unsafe to approach a stream bank to collect a sample manually due to the presence of high flows or in stormwater drains that can have flashy unpredictable flows. Also, in some instances it may be necessary to sample at regular intervals throughout a 24 hour time period or at times when it is not possible to collect them manually. In these situations it is appropriate that an automated sampler be used to collect grab samples. Automated sampling devices include refrigerated or non-refrigerated automatic pump samplers and rising/falling stage samplers.

Automatic pump samplers, both refrigerated and non-refrigerated are comprised of a number of bottles in a carousel, a sample intake line that is fixed in place within the stream and connected to a pump or pumps, and a computer controlled data logger that requires programming. The equipment is programmed to be 'triggered' when a pre-entered set of conditions are met. For example: a certain stream height, time of day, change in temperature, the rate of rise or fall of the stream level, a particular turbidity reading or any number of possible programmable triggers. Once triggered, the automatic sampler starts sampling according to the program set. Installation of automatic samplers should be in accordance with manufacturer instructions. When using automatic samplers for taking water samples, it is important to adhere to the requirements for sample handling including sample holding times and sample containers for the parameter of interest (see Appendix C8). If using automatic samplers, the sampling lines (tubing or pipes) must be regarded as an intermediate container (see section 3.1.1), and the possibility of exchange between the sample and the walls of the lines must be considered. The time of contact between the sample and the wall material is important, and residues of previous samples must be properly flushed out before liquid is delivered into the sample container. More detail on this aspect is given in AS/NZS 5667.1: 1998.

Automatic samplers also include remote samplers, such as rising-stage and falling-stage samplers. In regards to sampling event-based flows in ephemeral or temporary waterways, only falling-stage samplers should be considered, as rising-stage samplers tend to sample first flush waters. If the data is to be used to determine locally-derived water quality objectives (as per ANZECC/ARMCANZ 2000) then it is recommended that in accord with the AusRivAS sampling protocols (see section 4.1) sampling takes place 4–6 weeks after a flood event and flow has been established.

Photo shows ISCO sampler and Ava anche fridge

**Figure 3.3 Auto-sampler**

With rising stage samplers, water samples are taken as the river level rises and samples can only be retrieved after the river level has receded (Figure 3.4). As the water rises it reaches the crown of the intake, flow starts over the crown and begins to fill the bottle. Sample bottles fill progressively from bottom to top. Sampling ceases when the level of the water in the bottle reaches the inner end of the air exhaust, which then prevents circulation through the sampler. An air lock forms in the intake and prevents enrichment of the sample from water flowing back and forward and transporting sediment into the sample container.

**Figure 3.4 Rising stage sampler**

Rising stage samplers do not involve refrigeration and because samples are exposed to light and ambient temperatures they are only valid for total nutrient and sediment analysis. Note however that samples must be retrieved within a few hours for total nutrient analysis to be valid (particularly for N). Rising stage samplers are useful for collection of samples from flashy, intermittent streams at remote or sites that are not easily accessed.

Sampling units must be securely mounted, one above the other, with adequate support provided to prevent dislodging by large logs and other debris. Samplers should be erected and installed so that they are pointing in a downstream direction (ensure bottles are facing upstream). Sampler location is recommended in the following areas:

- on the inside of river bends (debris tend to be swept to the outside of bends)
- adjacent and mid stream of large trees (providing partial protection)
- downstream of small shrubs and trees (provide partial protection).

Each visit to the site should also involve inspecting sampling units for evidence of insects in the intake and breathing tubes, a common reason for missed samples (and contamination).

### 3.1.3 Field filtration equipment

For some characteristics listed in Appendix C8, the samples must be filtered in the field before they are placed in the container used for transport to the laboratory. Depending on the characteristics being measured, either vacuum or pressure filtration equipment may be needed.

An important factor in field filtration is to note that the equipment used for the filtering task is an 'intermediate container' and as such the equipment is a potential source of contamination of the sample (see section 3.1.1) so that pre-rinsing and the use of field blanks (see section 2.3.6) is advisable.

Vacuum filtration is recommended for chlorophyll samples; the pressure difference across the filter should not exceed 40 cm of mercury to prevent lysis (rupturing) of the cells. You need to filter a known volume of the water and send only the filter paper to the analyst (see Appendix C8). The equipment comprises a vacuum flask, vacuum pump, sintered glass filter funnel and a supply of the specified filters. It is not essential to filter the volume shown in Appendix C8; usually, only one filter paper needs to be submitted. It is essential to record the actual amount of water passed through the filter and report this to the analyst, so that the concentration can be calculated.

Pressure filtration is recommended for dissolved metals and some nutrient characteristics. The water passing through the filter is sent to the laboratory and the filter discarded. Typical equipment comprises a hand-operated syringe with a supply of 0.45 µm filters and, for waters with high suspended particle load, pre-filters (see Figure 3.5).

**Figure 3.5 Pressure filtration equipment**

Occasionally, a high content of suspended matter could make it difficult to filter the volume shown in the table. In cases where the aim is to give the analyst a stated volume of filtered liquid, the use of more than one filter might solve the problem. Alternatively, you could measure or estimate the volume actually filtered, and provide this information when submitting the sample.

### 3.1.4 Items for sample security

Ensure that you have an adequate supply of items such as sample seals, evidence bags, and locked storage boxes as detailed in section 3.7.1.

### 3.1.5 Sample carrier boxes

To keep samples at suitably low temperatures they are transported in cleaned/ uncontaminated insulated carrier boxes (coolers). These are kept cool by adding block or crushed ice, dry ice, freezer-blocks, or other similar substance, or are refrigerated by a power source.

Samples requiring refrigeration are generally packed in crushed ice. Crushed ice is used in preference to block ice as it can be packed in much closer contact with the samples.

Note: An acceptable alternative to crushed ice is a combination of crushed ice and 'ice bricks' (frozen containers of refrigerant solution having a freezing point not greater than 0°C), provided that the 'ice bricks' are in a frozen state when the samples are packed in the carrier, are completely surrounded by crushed ice, and are used only to lessen the amount of crushed ice required—not as the sole or primary means of cooling the samples.

Dry ice (solid carbon dioxide) is used where samples must be frozen immediately after collection. It is available in block and pellet form. Pelletised dry ice is preferable for the same reason as for crushed ice. A combination of block and pellets could also be used, the pellets being placed next to the sample containers. Suppliers of dry ice are listed in the telephone directory or can be found via web search.

An acceptable alternative is a transportable freezer, provided that the samples, once placed in it and frozen, are taken to the laboratory promptly, and care is taken to ensure that they do not thaw before delivery. In an emergency, samples can be frozen by surrounding them with a slurry of crushed ice mixed with common domestic salt (sodium chloride). This rapidly achieves temperatures well below 0°C.

When storing chilled or frozen samples in coolers, note that the coolers can be a source of sample contamination under some circumstances. For example, if a cooler has been used for storing fish, and is then used for storing samples collected for nitrogen or phosphorus, residual odorous substances from the fish (such as ammonia) can permeate the container walls, even if the container is of high density polyethylene (HDPE). If a cooler used for odorous material needs to be used for samples, be sure to clean it thoroughly before use.

If air transport of samples is involved, take account of air transport and company requirements regarding wet and dry ice.

Workplace health and safety—it is hazardous to transport dry ice inside a motor vehicle with all of the windows closed.

### 3.1.6 Marking pens

Only waterproof pens should be used for labelling. Marking pens used to label samples must have waterproof ink. Enamel paint pens are useful in this regard. Writing a label before taking the sample (e.g. dipping the bottle into a waterway) avoids the difficulty of trying to write on a wet label. Only write on dry labels, and carry spare pens.

Note that when sampling waters for the presence of solvent-type compounds, extra caution should be used as marking pens contain solvents and could contaminate your sample.

It is advisable to place labelled samples inside a plastic bag to protect the label details from rubbing or scratching off.

### 3.1.7 Camera

Photographs are useful when investigating pollution incidents. Check that you have appropriate spare items such as films, memory cards and batteries. Accessories such as glare/ultra-violet light filters, extra lenses or flash equipment could be appropriate in some circumstances.

Cameras that automatically imprint the exposure date and time on the photograph can be useful, but you need to be sure that the camera's clock is set correctly. This also applies to digital cameras.

When taking photographs, it is essential to clearly identify when and where each shot is taken. Shots may be numbered consecutively and descriptive notes made at the time. Where practical, include identifying features such as a sample label or placard within each shot.

Note that conventional photographic images on film or paper, and electronic image files produced by scanning or by digital cameras, can all be manipulated. Therefore, images intended for legal purposes should be stored in secure places to guard against unauthorised access.

### 3.1.8 Voice recorder

A voice recorder can be useful for immediate recording of your observations if circumstances make writing on paper difficult. If you use one, you should listen to the recording and transcribe it as soon as practicable.

### 3.1.9 Global positioning system (GPS)

A hand-held GPS can be useful in quickly recording the location of your sampling sites by storing them as waypoints. Hand-held GPSs are typically accurate to around 5 m, but this can change with cloud cover, altitude, tree cover, the number of satellites the unit can 'see' at the time of the reading and which map datum you have used (e.g. Aust Geod. 84, WGS84, etc.). The accuracy of your readings, and which map datum you have used should be recorded at the time of your GPS reading.

If you store positions as waypoints, you should note the waypoint number in your notebook while in the field, and transcribe the coordinates of each location from the GPS as soon as practicable. Some models of GPS can also be connected to a computer for easy download of waypoint data.

## 3.2 Labelling

Adequate sample description and labelling are extremely important in sampling (see Figure 3.6). Complete the labels at the sampling site and record details in your notebook. To guard against possible confusion between samples, each sample should be given a unique number. This number can be made up of parts containing codes for different pieces of information, if required. However, the label must include the following information:

- sample location
- sample number/label
- sampler ID
- date.

Figure 3.6 Typical label on sample bottle or jar

### 3.3 Sample containers and preservation methods

Ideally, analysis of samples should be performed in situ or at least on site. However, as this is usually not practicable, it is essential that you follow correct procedures for collection, preservation and transport of samples to a laboratory for analysis.

#### 3.3.1 Sample containers

This section applies to samples of wastes, waters and sediments. Handling and packaging requirements for animal and plant samples are discussed in Sections 3.5.4 and 3.5.5.

For samples of waters, wastes and bottom sediments, each sample should be collected and stored in a container appropriate for the quality characteristics of interest. However, if when investigating a pollution incident there is only one chance of taking the sample, and the specified type of sample container is not available, it should not be assumed that sampling is not worthwhile.

Appropriate containers and preservation methods are necessary to avoid risks of contamination of the sample and/or losses of analytes of interest during storage and transit prior to analysis. Details of sample containers and preservation are given in Appendix C8. These are based on Australian Standards AS/NZS 5667:1998 and AS 2031:2001 and overseas standards, with updating and other changes on the advice of Queensland Health Forensic and Scientific Services (QHFSS). The information in Appendix C8 is intended as a field reference with specific directions that can be followed without need for detailed knowledge of analytical procedures.

It is important that you follow these specifications exactly. If this is not possible, ensure you make a written record of what methodology you adopted.

The requirements listed in Appendix C8 include:

- the type of material/s suitable to contain the sample (container body and cap)
- the suitable method/s of pre-cleaning sampling containers
- preservation procedures
- maximum holding times
- comments on sampling procedures.

Containers should preferably be supplied by the laboratory, prepared as described in this manual and ready for use. Each container should already have a waterproof label attached with spaces for the user to fill in the appropriate details for the sample.

Prepared containers should preferably be supplied in sealed plastic bags with some type of tamper evident closure such as a suitable seal incorporating the laboratory's name (see Figure 3.7). All containers must be subjected to a quality control program to ensure their integrity with respect to the parameters being analysed.

**Figure 3.7 Sample bottles security sealed in plastic**

Once samples are taken, some of their quality characteristics can change naturally. To keep these changes to a practical minimum, for some analytes of interest specific chemicals such as acids are added as preservatives (see section 3.3.2 and Appendix C8).

If using an intermediate container, you should, ideally, have it prepared in the same way as the final one (e.g. acid-washed). If that is not practicable, and if you consider it essential to collect a sample there and then, at least ensure that the container is visibly clean, and report its preparation and use to the laboratory.

### **3.3.2 Preservation and storage**

For some quality characteristics listed in Appendix C8 there is a choice of preservation method. This is shown by a solid horizontal line separating the preservation details in the respective columns within the particular entry. A note below the name of the quality characteristic alerts you to this fact.

The amount of each preservative to be added is stated in one of these ways:

- until the sample pH reaches a stated range

or

- as an amount relative to the volume of sample; this amount is stated by mass (if a solid) or by volume (if a liquid)

or

- as one or more multiples of a fixed amount relative to the volume of sample, until an observable condition is met. For example, the system for preservation for metals analysis incorporated in Appendix C8 was designed to make the added preservative approximately one per cent by volume in the sample given to the laboratory.

Preservatives should preferably be supplied in small vials sealed in plastic bags, as described above for sample containers. The vials (e.g. Figure 3.8) should be labelled with the following information:

- preservative type and quantity
- preservative expiry date
- batch number
- hazard warnings if necessary.

Sometimes sample containers are supplied with preservatives in situ. This may be in the form of a small volume of liquid or crystals inside the empty container (for example, sodium thiosulphate crystals inside sterile jars intended for taking water samples for bacteriological testing). Check the supplier's labelling in respect of included preservatives. Should included preservatives be present, then care is needed to prevent loss of preservative when filling the container, for example, avoiding overfilling or spillage.

If your sample volume is different from the stated 'typical volume', you must ensure that the proportion of preservative to sample remains at the intended ratio or greater.

For characteristics where the Appendix C8 tables show 'Refrigerate' or 'Freeze' in the column headed 'Storage conditions', the appropriate temperature range is shown in the table heading. The sample should be cooled to this range as rapidly as is reasonably practicable and kept within that range until analysis commences (Note: AS/NZS 2031:2001 indicates 2–10°C for refrigeration).

Figure 3.8 Example of preservative container for preservation of samples

### 3.4 Preventing contamination

Avoiding sample contamination is an important aspect of sampling. There are always potential sources of contamination, and the aim should be to keep the risk of contamination to a practical minimum, consistent with the types of analytical tests required. Possible sources of contamination include:

- Sunscreens (zinc oxide) or insect repellents (organic chemicals) on skin could contaminate a sample if transferred by some unintentional means to the material sampled.

- Where samples are being taken for both metals and nutrients, there is risk that nitric acid (used as preservative for the metal samples) could contaminate the nutrient samples. Precautions could include keeping the acid container closed while collecting nutrient samples, or having a different person collect each group of samples. More information on sampling for nutrients is given in Wruck and Ferris (1997) and QHSS (1998).
- Residual sample material from previous tests could give incorrect readings when measurements are being made with field instruments. Special attention should be given to probe and test kit item rinsing after each field measurement in order to prevent future contamination. See section 3.1.1 concerning intermediate containers.
- Avoid smoking and wear Nitrile gloves at all times.
- Corrosion and oxidation of metal components in probe cathodes, electrodes and membranes could contaminate a sample and yield inaccurate readings.
- Note that some container caps have inserts; never touch the inserts with the skin or remove them from the caps.
- Cover work spaces used for sample handling (e.g. vehicle tray or tailgate) with new alfoil or plastic to provide a clean working surface. Replace it after driving to a new site.

### 3.5 Collecting samples

Figure 3.9 summarises the steps in the general procedure for samples of wastewaters and surface waters.

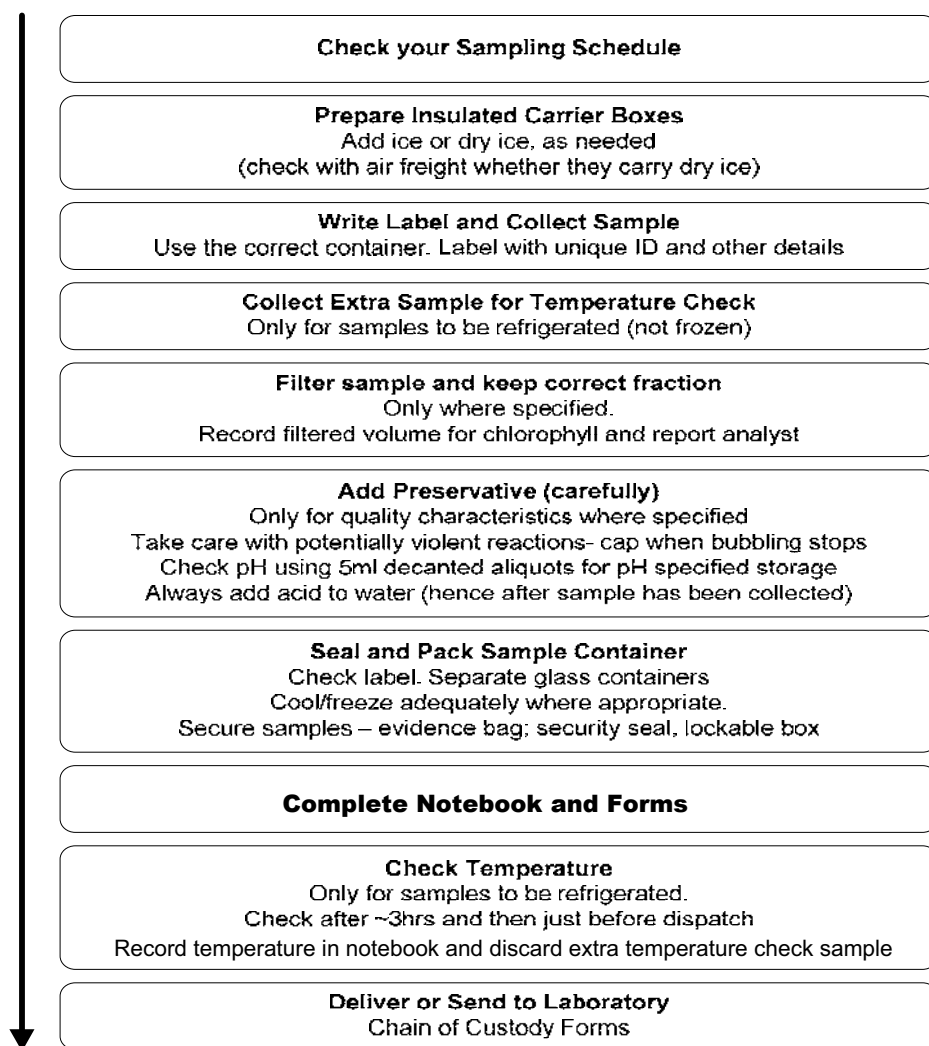

Figure 3.9 Steps in the sampling procedure

Further detailed directions and tips for these steps can be found for some sample types in the relevant subsections.

### 3.5.1 Surface waters

Using a waterproof pen, complete details on the label attached to the container, if possible before you collect the sample; details of labelling are addressed in Section 3.2. Be sure to let the ink dry completely before immersing the container. You might also use a strip of waterproof tape fastened around the container to ensure the label does not become detached (one end of the tape adhering to the other), and place the container into a plastic bag.

If practicable, collect the sample directly into the sample container, holding it either by gloved hand or by means of a sampling rod. If this is not practicable, collect the sample with a sampling beaker and transfer it promptly to the sample container, but beware of contamination (see Section 3.1.1).

If sampling from an open channel, try to take the sample in the centre of the channel, where the velocity is highest. Hold the mouth of the sampling container well above the base of the channel, to avoid disturbing and picking up any settled solids.

If the water depth permits, the mouth of the sample container should be held approximately 10 cm below the water surface. The surface layer of water often comprises a lipid-rich surface microlayer that may contain organic contaminants many times more concentrated than the water just below the surface.

Keep your hand out of the flow as much as possible to minimise risk of contaminating the sample, or causing infection or other harm to yourself. If the sample is to be analysed for substances present in 'low' concentrations—for example, nutrients—any contact of your skin with the sample should be avoided. If sampling from a boat in shallow waters, beware of stirred up sediment created by the turbulence of the boat's movement. If this happens, do not collect the sample as soon as the boat arrives at the site. Wait until the sediment has settled. If sampling in deeper waters, avoid taking a sample in or near the wake. Take the sample from ahead using a pole, or intermediate container.

To avoid labels rubbing off sample bottles while stored and transported in eskies filled with ice, it is advisable to place bottles within individual zip-lock bags.

Avoid:

- scraping the walls of drains, tanks, sewers, and so on; this could dislodge adhering matter into the sample, and so make it unrepresentative
- disturbing sediment, if sampling in shallow waters; this could also make the sample unrepresentative of the water column.

Do not:

- smoke during operations
- rinse sample containers with waters or wastes being sampled
- risk loss of preservatives by overfilling sample bottles.

Should a problem arise while you are collecting a sample—for instance if your sample becomes contaminated by floating fats in a waste pond or disturbed sediments in a stream—use a fresh sample container and start again.

It is preferable to use the unique sample ID number rather than write descriptive text on labels. You must record the descriptive text in notes for future reference.

If taking **microbiological samples** from a body of water that has enough depth to immerse the sterile container, hold the container by the sides and keep it nearly upright as you lower it into the water, so that it fills without spilling any pre-added sodium thiosulphate preservative from the sample jar (if present). For situations where it is not practicable to immerse the sterile container in the water or wastes to be sampled, you might need additional equipment as follows:

- an intermediate container that can be dipped into the water or wastes and that can be sterilised (by flaming) in the field immediately before use—for example, a stainless steel jug
- a means of sterilising the intermediate container—for example, a portable butane or propane burner. AS 5667.1 states that methylated spirit flames should not be used as they are not hot enough and are difficult to control. NOTE: Flaming involves a risk of causing serious injury to people and damage to property. While flaming the jug, hold it by the handle with a sampling rod, piece of rag, or other suitable insulating material; if using a rag or other combustible material, take great care you do not set fire to it. Transfer the sample immediately to the sterile sample container. Turn out the flame as soon as you are finished.

If sampling **temporary waters**, refer to [Appendix C4](#) for further information.

If sampling for **suspended solids or nutrients** refer to [Appendix C10](#) for further information on sample collection with different types of sampling equipment.

If collecting bulk water samples for use in **direct toxicity assessment** (DTA) laboratory trials, refer to Appendix C5.

When completing your notebook, record the following sample details even if already included in a sampling schedule:

- name of the sampler
- date and time of sampling
- details of sample location and source
- quality characteristics to be determined
- container type (volume, washing, material etc.)
- sample volume collected
- preservation method used
- serial numbers of seals affixed to sample container
- unique sample identification number (a different number for each sample container and package)
- any other details relevant to the sampling, for example, photographs by number.

### 3.5.2 Groundwaters

Groundwater sampling requires special equipment for sampling from a bore-hole or well, for example, a suitable bailer or pump, and a procedure to ensure sampling of fresh recharge water from the aquifer. Sometimes special precautions are needed to prevent changes in quality of the groundwater due to effects such as:

- reduced pressure when brought to the surface: this can cause gases in solution at the higher pressures underground to be evolved – in some cases, these can be toxic gases, such as hydrogen cyanide if the groundwater has been contaminated by cyanide solution
- exposure to components of the atmosphere such as oxygen; this can oxidise compounds naturally present in the reduced form (for example, ferrous ion).

Collecting groundwater samples needs specialised knowledge. If you need to take groundwater samples and have not been trained to do so, it is recommended that you refer to AS/NZS 5667 11 1998 (Water Sampling Guidelines—Part 11 Guidance on sampling groundwaters).

Sampling groundwater for microbiological examination requires the normal precautions mentioned above, plus the precautions for preventing microbial contamination of the sampling equipment and the sample applicable to surface waters sampling (section 3.5.1). If you need to collect such samples, you should obtain advice from reliable sources such as those cited above.

### 3.5.3 Sediments

Sediment samples are typically more heterogeneous than water and wastewater samples. This means special care is needed in removing sediment samples from a stream bed. It also means that a composite sample is more likely to be appropriate than a single sample.

For detailed advice on sediment sampling, refer to AS/NZS 5667.12:1999 'Guidance on the Sampling of Bottom Sediments' and Simpson *et al.* 'Handbook for Sediment Quality Assessment 2005 (CSIRO)'.

General rules when sampling sediments include:

- If direct collection into a sample container is impracticable, use a suitable mechanical device such as a stainless steel grab, dredge, or corer, washed in waters at the sample site.
- If the sample is NOT to be frozen, fill the container almost to the brim. Chill samples in ice or refrigerate promptly.
- If freezing of samples IS required, fill the container to only two-thirds of capacity, including any cover water taken from the same site. Place samples promptly in dry ice or portable freezer.
- It may be necessary to sample sediments from temporary waters such as intermittent streams or ephemeral streams. In such cases you should refer to Appendix C4.3.2 for further guidance.

### 3.5.4 Fish and other aquatic animals

Public complaints of 'fish kills' are a common reason for taking samples of aquatic animals. The Fish Kill Reporting and Investigation Manual (DEH, 1998) contains detailed advice on collecting these samples. The information below is a summary.

#### How many to collect

Usually, there will be many more fish than you need to collect for analysis or examination. In such cases, if some fish appear to be still alive (e.g. some might be moving but showing signs of lethargy or distress), choose them rather than those that already appear to be dead (such as any that do not move when touched, or any showing signs of decomposition, for example odour). Nevertheless, if only already-dead fish are available for sampling, they are suitable for chemical testing (but not histopathology).

Under the *Animal Care and Protection Act 2001*, approval from an Animal Ethics Committee is required for the sampling of live fish for scientific purposes. If approved, the handling of fish collections should be consistent with the guidelines set out in the Animal Care and Protection Act. Subject to approval, the euthanasia of aquatic fauna via chilling is a widely accepted technique consistent with preserving sample material and any related contaminants. A practical method of chilling for this purpose is to place the fish in a plastic bag of water and ice for 10 minutes or longer. In the case of fish from brackish or salt water habitats, the ice should first be placed into a separate plastic bag, in order to avoid rapid changes in salinity as the ice begins to melt.

The amount collected should be:

- for physicochemical analyses at least three whole fish (of the same species) of approximately uniform size if possible to allow valid comparison between sites. If the fish are small, you might need to collect more than three to get enough material for analytical tests. Collect as many as needed to provide:
  - for organic analyses such as pesticides, herbicides and PCBs—at least 250 grams (whole body mass)
  - and/or
  - for inorganic analyses such as heavy metals – at least 100 grams (whole body mass).

Note: As you might not know which contaminants are present, it is usually best to collect enough material for both types of analyses.

For histopathological examination:

- At least three whole fish (of the same species) of approximately uniform size if possible to allow valid comparison between sites. Note: histopathology requires live or freshly euthanased samples, or tissue samples preserved with 10 per cent formalin.
- Do not freeze samples.

See Part E of this manual for more detailed advice on taking and handling samples for veterinary examination.

### **Dissection of fish for samples of organs**

If physicochemical analysis of fish organs (such as gills, livers) is to be performed by the laboratory, the fish should be dissected and the organs separately packaged, labelled and preserved before despatch.

Cross-contamination of samples can easily occur if dissection is done without proper care. Reference to the Fish Kill Reporting and Investigation Manual (DEH, 1998) is strongly recommended.

### **Packaging and preserving**

Samples of aquatic animals and fish organs should be packaged according to the tests required as follows:

Physico-chemical analysis:

- Where poisoning by pesticides or organic compounds is suspected:
  - wrap specimens in aluminium foil with the dull side of the foil inwards
  - freeze as soon as practicable.
- For other analyses, including metals:
  - place samples in polyethylene bags or wrapping
  - freeze as soon as practicable.

Histopathological examination:

- If fish are dissected on site, follow directions in the Fish Kill Reporting and Investigation Manual for fixing the organs in 10 per cent formalin in plastic sample jars.
- Send to the histopathologist as soon as practicable.

See Part E of this manual for more detailed advice on taking and handling samples for veterinary examination.

### **3.5.5 Vegetation and algae**

Chemical analysis of aquatic or terrestrial organisms associated with the site of an incident can sometimes give information concerning the nature or source of a release of wastes or other source of contamination. For example:

- Plants could have accumulated a deposit or show discolouration on leaves or other parts.
- Aquatic plants can bio-accumulate metals and organics from the water column and the sediments.

- The leaves of emergent aquatic plants can bio-accumulate metals and organics from the atmosphere.
- Terrestrial plants can bio-accumulate metals and organics from the atmosphere and the soil.

Typical plant samples include leaves, bark and roots.

If vegetation surfaces (e.g. leaves) may have been contaminated by spray drift, consider wipe sampling (Section 3.5.6)

Plant samples should be packaged in a similar way to fish:

- If the sample is to be analysed for organics, wrap in aluminium foil with the dull side of the foil inwards, and chill or refrigerate.
- If the sample is to be analysed for inorganics, wrap in polyethylene bag or wrapping, and chill or refrigerate.

It may be necessary to collect samples from algal blooms for identification of the offending species. See part D of this manual for more detailed advice on taking and handling algal samples.

### **3.5.6 Wipe sampling of surface contaminants (also known as 'swab sampling')**

The presence of surface contamination (for example, by dusts, spray drift, or residues from containment) can be assessed by taking a swab from the surface concerned.

This is a useful technique for testing for the presence of contaminants on a surface. However, although there are regulatory measures of surface contamination for some contaminants (for example, for 'PCB-free' materials), the use of wipe samples for a purpose other than detecting contaminant presence (for example, comparing surface contamination on a spatial basis, for checking the efficacy of decontamination, or for comparison with environmental effects guidelines) is not recommended. In the latter case, the units are incompatible (surface contamination is measured in mass per unit area, and environmental effect levels are concentrations per unit volume or mass).

Wipe sampling is applicable for assessing surface contamination both from organic contaminants such as pesticides and from inorganics such as metals. Wipe sampling is most efficient on smooth surfaces such as glass, metal, painted surfaces, and smooth vegetation surfaces such as leaves. It is less effective on surfaces that are rough and/or porous such as timber and concrete.

There is no standard method for wipe sampling, although there are published standard methods for specific tasks (for example, ASTM E1728 for sampling lead dust from surfaces).

The design of a wipe sampling protocol involves choosing a material for the swab, a solvent to wet it, and a standard area to swab. A minimum of 100 sq cm surface should be wiped. If only trace levels of contamination are anticipated, wiping a much larger surface area is advisable, for example, up to a square metre. For wiping such large areas, more than one wipe may be used, and wipes can be pooled for analysis.

A variety of readily available materials are suitable for use as swabs. The portions of material chosen should be uniform in all respects and free of measurable contamination in respect of analytes of interest. The latter should be checked by analysing blank swabs. Examples of suitable swab material supplied in uniform packs are filter papers and small gauze pads such as those used for small wound dressing.

The wetting solvent of choice in most cases is an organic solvent such as isopropyl alcohol or hexane. Methylated spirits purchased in a glass bottle from a pharmacy can be used. Water is only appropriate for inorganic dusts. The purity of the solvent needs to be assured against the possibility that it is a source of any of the analytes of interest (for example, by testing a blank).

The sampling protocol should define a standard area for swabbing, as well as a standard method of taking the swab. For example, it might involve wetting each swab with 2 ml of alcohol, and wiping the swab across a pre-marked 10 cm x 50 cm surface from left to right until the whole surface has been covered, then wiping again from top to bottom, while applying an even pressure and holding the swab flat against the surface. An alternative to pre-marking a surface is to swab within the boundaries of a pre-cut template held against the surface (the template would need to be appropriately cleaned between sites). In the case of leaves, a uniform area could be approximated by swabbing the surfaces of a fixed number of leaves of similar size at each site.

Nitrile gloves should be worn and changed between sites, and used swabs sealed in labelled sampling containers appropriate for the storage of the analytes of interest, for example, a solvent-washed jar if pesticides are of interest.

### 3.6 Instrument-based field tests

To obtain accurate results for some quality characteristics, measurement on-site is necessary.

Typical field equipment used for this is:

- thermometer
- pH meter
- dissolved oxygen (DO) meter
- conductivity meter
- turbidity meter
- Secchi disc.

Some modern field instruments (multi-parameter instruments) can measure more than one quality characteristic, for example, both temperature and DO (see Figure 3.10). Note that not all field instruments give results of similar accuracy. It is important to check that the instrument used meets requirements and is calibrated (indicated by documentation of current calibration status).

Figure 3.10 Testing waters with a water quality meter

## **3.6.1 General guidance on taking field measurements**

### **3.6.1.1 Background**

Information in this subsection is provided to help you take water quality measurements in a scientifically valid manner so that the results will represent the field conditions fairly.

You should be familiar with the contents of the manufacturer's manual specific to any instrument that you use, specifically in respect of calibration, use of the instrument and any limitations. If the instrument is not in calibration or is used incorrectly the data is of dubious value.

### **3.6.1.2 Instrument maintenance and calibration**

Due to the variety of instruments currently available that perform these tests, it is not practical to provide instrument-specific advice on storage, calibration and maintenance in this manual. It is strongly recommended that instruments are stored, calibrated, maintained and used as per manufacturer's instructions.

As a general principle, calibration should be checked and recorded before, during and at the conclusion of field use.

It is essential that unambiguous written records are kept of instrument maintenance and calibration. See Box 3.1 for guidance.

### **3.6.1.3 Take multiple readings**

As with any other sampling, when taking instrument-based field measurements, multiple readings should be taken and recorded, and reference sites should be used to acquire background or 'normal' data for comparison purposes.

### **3.6.1.4 Keeping records of field measurements**

Because the results of field measurements could be used in court actions, it is important to carry out all measurement procedures in a precise, consistent and reliable manner.

The original records made during measurements should be entered directly in a notebook, in case they are required for presentation in court.

### **3.6.1.5 Response to atypical or non-complying instrument readings**

If readings appear atypical or non-complying (based on 'acceptable criteria' in the standard operating procedure for the instrument in question), the first step should be to check for equipment problems, such as a broken electrical cable or insulation, faulty probe, depleted batteries, etc. If equipment appears sound you might take extra measurements to confirm that the results are valid.

The value of calibration before and after instrument use, and the taking of measurements at reference sites are particularly important if atypical or non-complying readings are encountered at a site of interest.

### **3.6.1.6 Importance of general observations**

Your observations during measurements can be extremely important in assessing atypical events or long-term trends, especially when investigating pollution incidents. Such observations could include:

- atypical water colour or clarity (such as greenish, muddy, pale brown and cloudy)
- odours
- wind speed and direction

- surface scum
- heavy algal or plant growths
- dead or dying vegetation in waterways or on banks
- dead or dying fish
- flotsam
- dumped material
- nearby earthworks or other construction activity
- nearby agricultural activities
- nearby industrial establishments or wastewater treatment works.

As visible conditions could be difficult to describe accurately in words, it is strongly advised to take photographs if possible (but note that some films have known colour bias). You should keep a record of the photograph number on the memory card/film to avoid any later confusion.

**Box 3.1 Maintenance and calibration of water quality measuring instruments**

All instruments used for taking measurements in the field (e.g. pH, temperature, conductivity, dissolved oxygen) must be maintained and calibrated to ensure reliability and credibility of the data they produce.

The aim is to ensure that each instrument is maintained in a sound operating condition, is capable of operating at acceptable performance levels, will not deteriorate from lack of required servicing, and that the credibility of the data the instrument produces can be demonstrated (for example, by the production of maintenance records and calibration logs in evidence).

Manufacturer's recommendations should be the basis of maintenance and calibration, in terms of both methods and frequency. As a general principle, the calibration of an instrument should be checked before and at the conclusion of a sampling exercise. It may be advisable to also re-check calibration once or more during an extended period of use, and after transport between sites or other circumstances that may affect reliability. Such 'in-field' calibrations should be recorded in a notebook and later transcribed into the calibration log book for the instrument (see below). Variability in performance shown by such calibration checks before, during, and at the conclusion of a sampling exercise should be reported with the data.

Because 'in-house' calibrations rely on buffer solutions and other techniques, a 'cross check' calibration using a real water sample should be conducted from time to time. This is done using two or more instruments simultaneously to test a bucket of typical environmental water (e.g. from a creek). The readings of calibrated and reliably performing instruments should be consistent with each other for such a sample.

For each instrument the following procedures and documents should be established and kept up to date:

- a list of spare parts and suppliers/sources of repair (it may also be feasible for a realistic supply of user-replaceable items to be kept on hand)
- written inspection, maintenance and calibration schedules (based on the manufacturer's documentation and the usage pattern for the instrument)
- a log book in which is recorded inspection, maintenance and repair activities detailing dates and persons involved. This may best be documented as a ring file arranged in chronological order covering the service life of the instrument. Sample inspection/maintenance records are provided in Appendix C1
- a log book in which is recorded calibration activities detailing dates, times and persons involved. This may best be documented as a ring file arranged in chronological order covering the service life of the instrument. Sample calibration records (log sheets and charts) are provided in Appendix C1

(Box 3.1 continued next page)

- adequate supplies of calibration standards (if these are required) should be maintained and where applicable storage and shelf life requirements followed.

Some of the above documents may be combined, for example, the maintenance schedule could be combined with the maintenance records, and the calibration schedule with the calibration records.

It is strongly recommended that within each work unit the oversight of instrument inspection/maintenance/calibration be tasked to a specific person/s as an unambiguously assigned responsibility. Such assigned person/s would be expected to personally perform or supervise the performance of all tasks and completion of related records according to the established schedule/s for the instruments held by the work unit.

## **3.6.2 Overview of field measurements**

### **3.6.2.1 Temperature**

Accurate temperature measurements are required for accurate determinations of pH, specific electrical conductance, and dissolved oxygen. You need to be aware whether the instrument you are using compensates for factors such as temperature when measuring another parameter, or whether results need to be adjusted by calculation.

Stratification is common in summer months when surface waters are much warmer than bottom waters. Accordingly, unless the water is shallow (less than 0.5 metres) and flowing, take temperature readings at different (measured) depths.

Warm water is less capable of retaining dissolved oxygen than cold water. For this reason, temperature should be measured at the same place within the stream at which dissolved oxygen is measured. This allows the correlation between the two parameters to be observed.

### 3.6.2.2 pH

A pH of 7 is called neutral, above 7 is basic (or alkaline), and below 7, acidic. Strong mineral acids such as concentrated phosphoric acid can have pH less than 1; strong alkalis such as caustic soda solutions can have pH approaching 14.

### 3.6.2.3 Dissolved oxygen (DO)

The maximum concentration of dissolved oxygen (DO) in water under ambient conditions is typically within the range of about 6–10 mg/L, depending on the atmospheric pressure and the water temperature and salinity.

Dissolved oxygen concentrations are most often reported in units of milligrams of oxygen gas (O<sub>2</sub>) dissolved in each litre of water, i.e. mg/L (the unit mg/L is equivalent to parts per million = ppm).

An alternative measure is dissolved oxygen saturation (per cent). This is the percentage of dissolved oxygen concentration present relative to what the concentration would be if water at the specified temperature and salinity was fully saturated with dissolved oxygen. Most dissolved oxygen probes compensate automatically for temperature and salinity when calculating dissolved oxygen saturation in water (check the instrument manual). Note that under natural conditions such as high algal density during sunlight, super-saturation (more than 100 per cent DO) can occur.

Considerable differences between DO concentrations at the surface and in the lower depths can result from stratification of the water column, due to temperature or salinity effects. This effect is usually most pronounced in summer months when surface waters are much warmer than bottom waters. Accordingly, unless the water is shallow (less than 0.5 metres) and flowing, take readings at different (known) depths.

### 3.6.2.4 Electrical conductivity (EC)

Electrical conductivity (abbreviated EC, and often simply called 'conductivity'), the ability of water to carry an electric current, is used as an indicator of salinity and the concentration of dissolved salts in a waterbody.

The unit of measurement for conductivity is siemens (S) per unit of length. A commonly used example of this unit is microsiemens per centimetre (µS/cm). See Conductivity units and their abbreviations in Appendix C7 for further explanation.

Typical values of EC in µS/cm are:

- De-ionised water in equilibrium with the atmosphere approximately 1
- Potable waters 50–500
- Freshwater less than 1500 (varies widely between catchments)
- Seawater approximately 52 000

Note that conductivity varies with temperature, and values reported are usually those corresponding to 25°C. A difference of 5°C can alter conductivity by approximately 10 per cent. Many conductivity meters have compensation functions so that EC at 25°C can be read directly. However, if necessary, a manual correction can be made by using the formula

$$K_{25} = \frac{K_t}{1 + 0.019(t - 25)}$$

where  $t$  = water temperature °C where conductivity is measured

$K_t$  = conductivity at temperature  $t$  °C

$K_{25}$  = corrected (25°C) conductivity of the water

### 3.6.2.5 Relationship of EC to salinity and dissolved salts/solids

Confusion can arise from the fact that salinity is sometimes equated to one of the terms 'total dissolved ions' or 'total dissolved salts' or 'total dissolved solids', and that the same acronym (TDS) may be used for the last two terms. The following notes explain the distinction.

- 'total dissolved ions' is the sum of the ion concentrations. This sum is used in a formula to calculate 'total dissolved salts'.
- 'total dissolved salts' is determined by calculation from the results of analysis for common ions (e.g. sodium, calcium, chloride).
- 'total dissolved solids' is determined by filtering a sample, drying at a specified temperature, and weighing the residue. It includes non-ionised species if present (e.g. sugars, other organics, colloidal particles too small to be retained by filter medium), with the result that 'total dissolved solids' can be greater than 'total dissolved salts'.

For typical fresh waters, the approximate total dissolved salts can be calculated from conductivity using the formula:

$$TDS = 0.68 \times K_{25}$$

Where  $TDS$  = Total Dissolved Solids (in mg/L)

$K_{25}$  = conductivity of the water at 25 °C (in mS/cm)

Note—this formula is not appropriate for water of atypical content.

Salinity in parts per thousand (g/L) can be calculated from conductivity at 25 °C using the formula:

$$S = a_1(K_{25}) + a_2(K_{25}) + a_3(K_{25}) + a_4(K_{25}) + a_5(K_{25}) + a_6(K_{25})$$

Where  $S$  = salinity in parts per thousand (g/L)

$K_{25}$  = conductivity of the water at 25 °C (in mS/cm)

$$a_1 = 4.980 \times 10^{-1} \quad a_2 = 9.540 \times 10^{-3} \quad a_3 = -3.941 \times 10^{-4}$$

$$a_4 = 1.092 \times 10^{-5} \quad a_5 = -1.559 \times 10^{-7} \quad a_6 = 8.789 \times 10^{-10}$$

### 3.6.2.6 Turbidity

The turbidity of a water body is a measure of the presence or absence of soluble, suspended and colloidal particles that hinder the transmission of natural light from the surface to the lower depths. Turbidity affects the potential rate of photosynthesis, and hence the growth of plants or algae in the water body.

### 3.6.2.7 Water clarity

The clarity of a water body is an indication of the presence or absence of suspended and colloidal particles that hinder the transmission of natural light from the surface to the lower depths. Clarity affects the potential rate of photosynthesis at any given depth, and hence the growth of green plants or algae in the water body.

This method is based on the common experience that the deeper a submerged object is, the less easy it is to see from the water surface, and the more cloudy the water, the less easy to see at a fixed depth. It entails the use of a Secchi disk (see Figure 3.11 and Figure 3.12) and is a relatively simple and quick way to obtain a measure of clarity, without the need to take

samples and analyse them for turbidity or suspended solids. The Secchi disk also has the advantage of integrating turbidity over depth (where variable turbidity layers are present).

**Figure 3.11 Testing clarity of water using a Secchi disk**

A Secchi disk is not appropriate for use in shallow waters where the disk can still be seen when resting on the substrate. In such cases you should use a turbidity meter or take water samples for laboratory analysis.

NOTE: The observer's visual acuity will affect the perception of the disc. It should be observed with 'corrected vision' (spectacles or contact lenses if these are normally worn) and not be performed on the side of the boat casting a shadow. Tinted lenses or sunglasses should not be worn, as they could affect the depth where the disc is recognised.

### 3.6.2.8 Chlorine (free, combined, and total residual)

Chlorine is widely used for disinfection of public water supplies, swimming pools, and treated wastewaters. Although the role of chlorine addition in water treatment is to disinfect (kill pathogens), some of the added chlorine can be consumed in reactions with oxidisable substances present in the water including ammonia, nitrite, and organic matter. 'Chloramines' are a common product of such reactions, which also deplete the chlorine available to kill pathogens. The reaction products are generally less effective disinfectants than chlorine, but are more persistent.

Chlorination treatment of water or wastewater usually involves the addition of a measured dose of one or more of chlorine gas ( $\text{Cl}_2$ ), hypochlorite ion ( $\text{OCl}^-$ ), and hypochlorous acid ( $\text{HOCl}$ ). The addition of chlorine gas alone results in a mix of all three in proportions dependent on factors such as pH and temperature.

The term 'free chlorine' is used to refer to the total concentration present of dissolved chlorine gas, hypochlorite ion, and hypochlorous acid, each of which has good disinfection capability.

The term 'combined\_chlorine' is used to refer to the chloramines, and the term 'total\_residual chlorine' is the sum of 'free chlorine' and 'combined chlorine'. These are the terms used in the Australian Guidelines for Water Quality Monitoring and Reporting (ANZECC/ARMCANZ 2000). Other terms for these mixtures of chlorine-containing substances may be encountered, for example some environmental authorities (EAs) include quality specifications for 'free chlorine residual' in an effluent. The term 'residual' refers to chlorine (as the total concentration of dissolved chlorine gas, hypochlorite ion, and hypochlorous acid) remaining after added chlorine has reacted with wastewater constituents. Thus 'free chlorine residual' is equivalent to 'free chlorine'.

The quality specification for chlorine (free, combined, or total) in an EA is usually the concentration measured at the outlet of a 'detention tank' designed to provide contact between the chlorine and the wastewater for a stated period to enable disinfection to occur prior to release.

Because the levels of 'free chlorine' relative to 'combined chlorine' can change over a short period of time, it is usual to measure chlorine in situ using a test kit or probe attached to a water quality meter. There are more sophisticated and accurate laboratory based methods available but these are generally not practical for field use.

Test kits commonly used for in situ chlorine testing are based on a colorimetric system, involving the addition of a chemical (DPD, typically supplied in the form of tablets in a sealed containment) to a fixed volume of sample water and measuring the intensity of pink colour produced by the reaction of the DPD with chlorine present in the water. The methods used to measure the colour intensity vary between kit types. Simple kits involve comparison by eye of the colour intensity with a calibrated chart or filter. More sophisticated (and accurate) kits measure colour intensity digitally. The results from DPD-based test kits may be adversely influenced by colours and interferences from chemicals present in the waters being tested (see section 3.6.3).

If using a DPD kit, it is essential to ensure that the DPD tablets are fresh (hard), that the seal is intact, and within the expiry date. The kit directions for use must be followed exactly, and cells and colour filters etc. kept scrupulously clean. Residues from previous tests can give false readings for subsequent tests.

### 3.6.3 Test kits

A range of commercial field kits are available for rapid testing of water quality. These include tests for analytes such as pH, metals and nutrients (among others). Test kits are a substitute (surrogate) for a range of instrumental techniques of which probes are just one. These kits can provide valuable on-the-spot information, although caution is advised in their use. It should not be assumed that a test kit will perform as specified by the manufacturer.

There are many factors which influence any instrument's performance. Test kits are often subject to a range of limitations and interferences depending on the type and nature of water being analysed (sample matrix). It is imperative test kit performances are initially verified to ensure they are fit for their intended purpose. This can be achieved by undertaking validation experiments covering the analytical range and the matrices being investigated. Once validated, acceptance criteria can be ascribed to the various tests. These acceptance criteria may or may not align with the manufacturer's specifications. Some level of quality control, such as use of check standards, must be utilised and monitored each and every time they are used.

It is important to remember the following points:

- Test kits are utilised in field environments and can be subjected to extreme physical conditions which will impact on kit performance. How do you know the test kit is functioning adequately? Has its performance characteristics changed since the last time it was used?
- Most kits have expiry dates for reagents that should be checked and adhered to.
- Test kits will require storage in an appropriate fashion (e.g. within certain temperature ranges; out of direct sunlight).
- Test kits often have varying levels of accuracy (e.g.  $X \pm y$  units). Will this accuracy suit your application? (e.g. will the accuracy of this kit allow you to differentiate between sites?).

- Test kits often have varying detection limits (i.e. only detect down to a certain concentration). If comparing to guidelines/standards/benchmarks, does the kit report within the range of these documents?
- Test kits can behave differently in fresh, waste and salt waters.
- Water containing particulate or suspended matter (even at small concentrations) can severely impact on the test kit producing a reliable result. For these types of samples, they should be filtered appropriately before using the test kit.
- Different brands of kits may vary in all of the above points.

N.B. It is NOT advisable to rely on test kits for data that may be required for legal purposes.

### 3.7 Sample security and transport

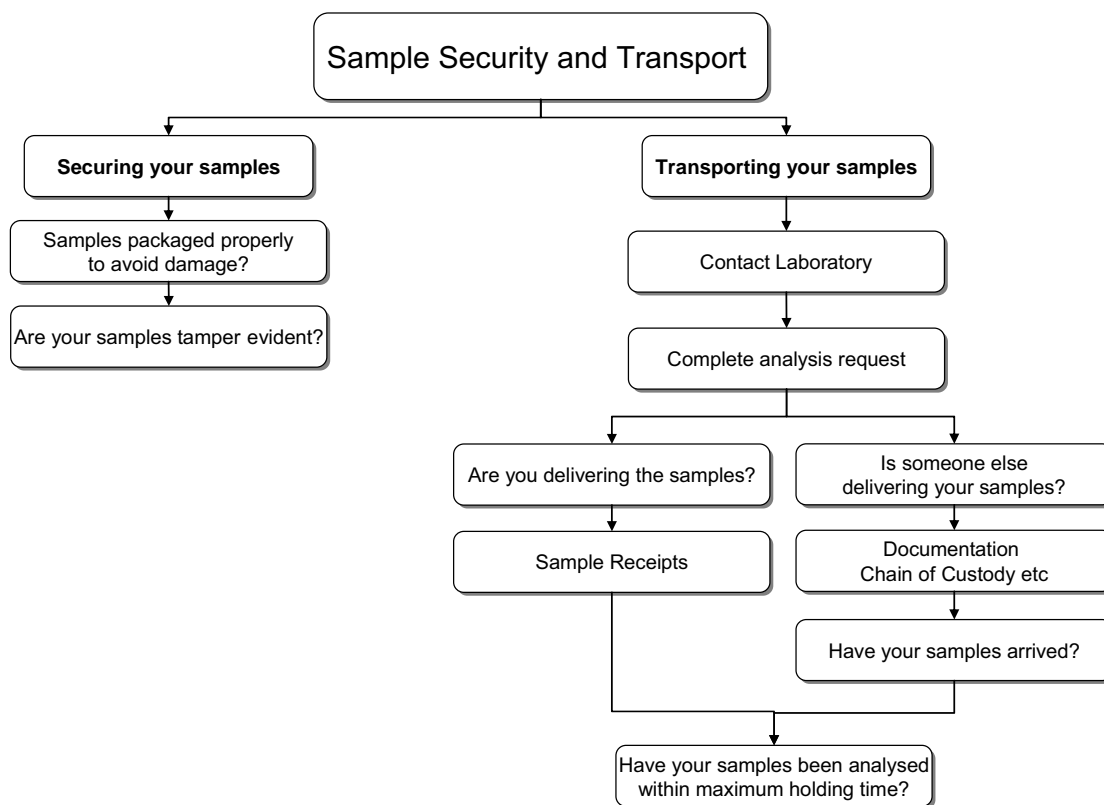

Figure 3.13 Overview of the components of a sample security and transport system

#### 3.7.1 Securing your samples

It must be possible to demonstrate that there was minimal risk of the sample having been interfered with between the time of sampling and the time of analysis. This requires a well designed system for security of the samples, including precautions to make any such interference evident upon receipt by the analyst. The system described in this manual is summarised in Box 3.2 and should be adequate for most purposes.

##### 3.7.1.1 Sample seals or evidence bags

Sample seals and evidence bags can be obtained from a range of commercial suppliers.

Typically seals are specially printed self-adhesive ‘security’ labels, designed to be affixed across the body and cap of the sample container. Each seal is made of a ‘self-destruct’ material so that any attempt to remove it will result in its disintegration so it cannot be re-affixed in its original condition. Each should have a unique seal number. Uniquely numbered and tamper-proof tough-plastic ‘evidence bags’ are commercially available in a range of sizes.

When you are issued with seals and evidence bags, you are responsible for keeping them in a secure place. At any time you must be able to account for the numbers received, the numbers used, and the numbers still in your possession. Include the seal/evidence bag number and the sample identification number when recording details of samples. Refer to Figure 3.14 for examples of security labels and seals.

**Figure 3.14 Examples of security labels and seals**

### 3.7.1.2 Locked carrier boxes

One way to hinder unauthorised access to samples is to use a system of insulated carrier boxes fitted with locks that can be opened *only* by:

- an appropriate staff member of your organisation having authority to do so
- the analyst or other laboratory staff member having similar authority.

If using such a system you should be able to testify in court that the keys were kept in secure places.

A person wishing to interfere with samples might try to remove the lock and later replace it without leaving evidence of their actions, such as cuts or holes in the box or the lock assembly. Each lock should be fitted to make this as difficult as practicable. Any attempt at access should leave evidence that laboratory staff will notice.

Each lock should preferably be a part of the body of the carrier box, or a padlock that fastens a hasp and staple assembly permanently fitted to the body. The two parts of the assembly would need to be fastened by, for example, suitable rivets, rather than screws that could be removed and replaced without leaving evidence of the fact. Padlocks should preferably be case hardened to resist cutting by a hacksaw.

## 3.7.2 Transporting your samples

### 3.7.2.1 General

After collecting the samples, you must have them transported to the appropriate laboratories, ensuring that the integrity of the samples is maintained. You can do this by:

- delivering them personally
- having a work colleague deliver them
- sending them by commercial carrier (such as road transport, air cargo)
- other reliable means.

Whatever means you use, the following points are important:

- Sample containers and packages need to be packed in sample carrier boxes to minimise the risk of breakage, leakage or spillage during transport.
- Sample carrier boxes must be handled and stored so as to protect the samples.

- Appropriate security measures must be in place.
- Documentation must accompany the samples.

If samples are transported by an air carrier, they are subject to the International Air Transport Association (IATA) Dangerous Goods Regulations. These regulations are updated annually, and failure to comply with them can lead to prosecution of the consignor. It is wise therefore to consult the airline company or the Civil Aviation Safety Authority (CASA) before sending samples, to check that the sample packaging (including the carrier box) and the labelling of the carrier box meet the requirements.

If you give samples to someone else for transport, such as a commercial carrier, it may be wise to contact them at reasonable intervals afterwards to check on the actual location of the samples, or whether they were actually despatched (by road or air, for example) at the time necessary to ensure delivery within the recommended maximum holding time.

Samples should be analysed within the maximum holding times specified; otherwise the analyst must report on the probable effect of the delay.

### 3.7.2.2 Transport precautions

Take the following precautions when preparing samples for transport:

- Re-check caps on containers to make sure they are tight and properly sealed, so that if any should fall over they will not leak. If necessary, tighten cap, re-tape and re-seal.
- Separate glass bottles from each other to prevent physical contact, which could cause breakage.
- If you use a transportable freezer to freeze samples in the field, but need to transfer them to an insulated sample carrier for transport (for example, by a freight contractor), add dry ice to the sample carrier to keep the samples frozen during transport. Contact the freight company (air or land) to discuss refrigeration options for your samples if required.
- Ensure that the following legends are plainly readable on the sample carrier boxes:
  - 'FRAGILE'
  - 'HANDLE WITH CARE'
  - 'THIS SIDE UP'
- To minimise thawing of ice or dry ice, protect samples from heat; for example, do not leave sample carrier boxes in the sun for long periods.
- Carrier boxes containing dry ice must not be hermetically sealed. Venting must be provided to release the carbon dioxide gas generated.
- Make every effort to minimise delays in transporting samples.
- Complete chain of custody documentation (Appendix C1).
- Where samples are carried by air, the carrier box must be leak-proof, and must have labels and complete documentation as required under the IATA regulations.
- Ensure that the laboratory will receive the completed analysis request either with the samples or earlier (for example, by fax or email).

**BOX 3.2 Summary of sample security system*****What the sampler does:***

Collect sample.

Place sample in labelled container and put cap on container.

Fasten security seal across lid and container or place sample in security bag.

Put sample in sample carrier box (cooler or other type) or freezer.

Secure carrier box or freezer by:

- a lock

or

- a padlocked chain, fastened around the body so that the lid cannot be opened without unlocking the padlock or cutting through a chain link or padlock.

NOTE: the chain links should be of welded construction (NOT able to be opened and closed using pliers) and the padlock body should be a solid casting (NOT laminated from sheet metal). Padlock and chain should preferably be case-hardened.

Give sample carrier box or freezer to transport carrier with chain of custody sheet (Appendix C1) attached and get receipt (on consignment documents).

Fax or email the completed analysis request to laboratory.

***What the laboratory does:***

Receive sample carrier box or freezer from transport carrier, complete chain of custody sheet and give receipt (on consignment documents).

Check:

- locks and chain are intact
- there are any other signs of tampering with the carrier box or freezer.

Unlock sample carrier box or freezer and remove sample container/s.

Check:

- all samples stated in the completed analysis request are present
- security seals are intact
- there are any other signs of tampering with the samples.

If there is reason to suspect tampering, contact sampler immediately and give details.

Determine whether samples should be analysed or not.

Record results of checks and any action taken because of them.

### 3.7.2.3 Addresses for despatch

It is suggested you keep a list of names, addresses and contact numbers (phone, fax and email) of appropriate staff at the laboratories that your organisation employs to perform analyses, for ready reference in the field. Appendix C6 contains space for you to enter these details.

### 3.7.2.4 Delivery of samples

The receiving laboratory should be advised in advance that samples are to be dispatched. If you notify the staff by mail or facsimile, you should get an acknowledgement. Only in exceptional circumstances should you send samples without this prior notification.

Samples delivered to the laboratory must be handed to a supervisor or other appropriate responsible staff member. This person should acknowledge receipt of the samples by signing the consignment documents accompanying each sample carrier box, chain of custody documentation or other appropriate form of receipt.

On receiving samples, the analyst must first check the contents against the analysis request, noting:

- the time and date when the samples were received
- whether the carrier box was locked when received
- any irregularities such as breakages or missing samples
- the condition of the samples—whether they are frozen, and if not, their temperature
- the condition of the seals and tape on sample containers and packages.

The purpose of this is to check on how well the samples were preserved, and whether there are any signs of tampering. The analyst must contact the sampler promptly if there are any signs of tampering or other irregularity, such as missing samples, broken or damaged containers, thawed samples that should have still been frozen, or samples at room temperature instead of chilled. In such a case, you should discuss with the analyst and decide whether analysis should proceed or whether you will re-sample. Keep a record of the discussion.

The analyst's report should include details of the condition of the samples on receipt. If any irregularity was discovered on receiving the samples, the analyst must also give details of this.

### 3.8 Laboratory analysis

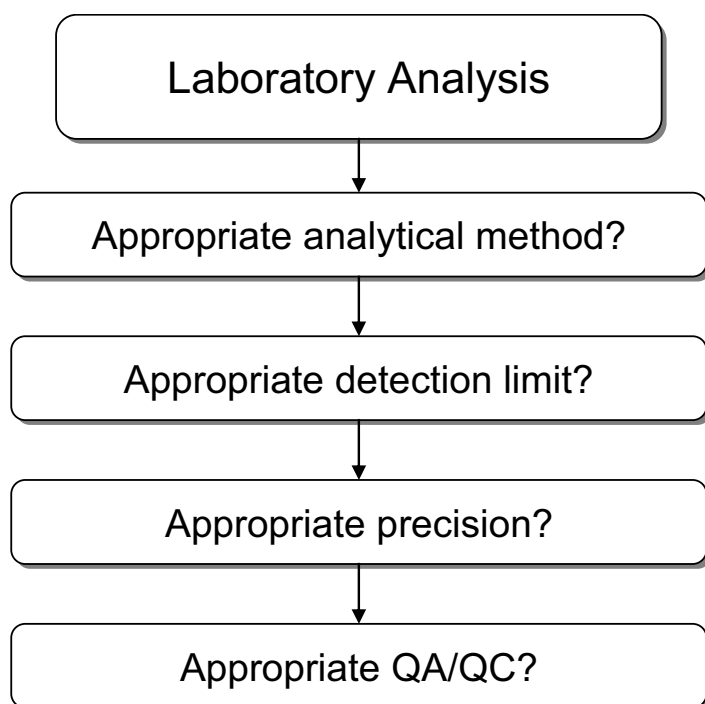

Figure 3.15 Essential laboratory analysis components for incorporation into a sampling protocol

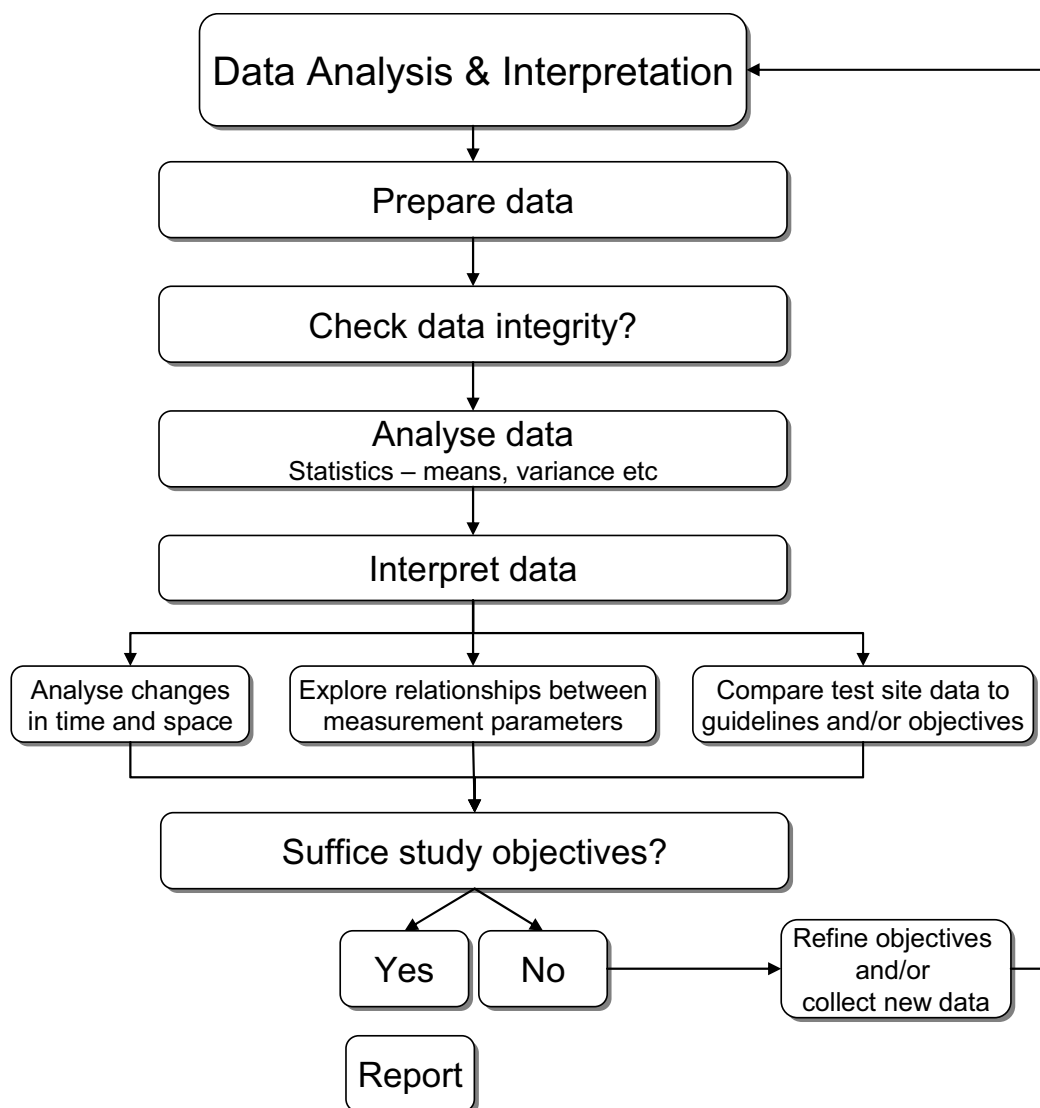

#### 3.8.1 Selection of analytical methods

Unless otherwise prescribed, samples should be analysed, as a minimum, in accordance with a method specified in one of the following reference texts (see References section):

- APHA AWWA Standard Methods for the Examination of Water and Wastewater (current version)
- USEPA (current version)
- ASTM, Annual Book of ASTM Standards (current version)
- relevant Australian Standards published by Standards Australia, as amended from time to time
- relevant ISO Standard (current version).

The method of analysis should be chosen by the analyst so as to be appropriate to the type of sample and to the expected concentration range of the constituent to be measured. The methods used by a laboratory should be verified or validated (for example, by using standard reference materials or standard addition techniques) and preferably be a method accredited by the National Association of Testing Authorities (NATA) or shown to be at least equivalent. Alternative methods to those described in the reference texts can be used provided that the analyst can validate the alternative method and prove that the results so obtained are equivalent to the results obtained using the prescribed method within the limits of the accuracy stated for the prescribed method.

### 3.9 Data analysis and interpretation

**Figure 3.16 Essential data analysis and interpretation components for incorporation into a sampling protocol**

#### 3.9.1 Sources of reference values

Once you have results from field measurements and laboratory analyses, you will need to be able to draw some conclusions based on sound scientific reasoning. The following resources act as a guide to the levels and indicators of water quality that your results should be compared against.

Reference documents useful for benchmarking environmental water and sediment quality data:

- ANZECC/ARMCANZ (2000) Australian and New Zealand Guidelines for Fresh and Marine Water Quality
- Environmental Values and Water Quality Objectives scheduled under the EPP Water, available through the department's website at Schedule 1 of EPP Water (including plans)
- NHMRC (2004) Australian Drinking Water Guidelines

- NHMRC (2008) Guidelines for Managing Risks in Recreational Water
- DERM (2009) Queensland Water Quality Guidelines
- Queensland Environmental Protection (Water) Policy 2009.

### 3.10 Data custodianship, management, and submission for regulatory purposes

Reliable and defined custodianship and data management is essential to ensure data is collected, maintained and used appropriately.

Data typically relates to measurements or statistics from measuring devices or observations, usually presented in a numerical or structured format. A collection of data may be referred to as a dataset, usually held electronically in databases (either as a collection of related data stored together in one or more computerised files, or an electronic repository of information accessible via a query language interface).

Generic classification of data includes time series data, spatial data and metadata:

- Time series data are a set of observations, results, or other data obtained over a period of time, often at regular intervals.
- Spatial data are data that refer to specific geographic areas. Records would generally include a geographic reference, for example, map references, latitude and longitude references, river catchment areas, local government areas, or others.
- Metadata is information which describes the content, quality, condition, and other appropriate characteristics of the data. The term information is a broader term often used to describe any data that is processed, organised or classified into categories, images, graphs, etc. for a designated purpose.

Good custodianship of data is needed to provide accountability for data sets and give users confidence with the level of integrity, timeliness, precision and completeness of data sets. All data, whether they are generated by government or obtained from an external source, must be managed by a custodian. A data custodian can be defined as a person or organisation that is responsible for ensuring specific data is collected, maintained and made available according to standards and policies or other licences, agreements or specifications.

Custodians are responsible for ensuring that the following minimum standards are applied to each dataset:

- documentation of the methods and process for data collection
- ensuring data is fully validated and quality assured with sufficient detailed metadata to enable its use by third parties without referring to the originator of the data
- the dataset must be recorded to enable the ownership, access constraints and licence conditions to be determined
- a contact for allowing the release or use of data by other parties.

There are a number of situations where individuals and organisations may need to submit water monitoring or other related data to the Queensland Government for the purpose of regulatory decision making. This could include but is not limited to purposes such as environmental impact statements, development approvals, environmental management plans and environmental evaluations.

In many cases, water monitoring data is required to be submitted electronically. The provision of correct and accurate data is the sole responsibility of the submitter and water monitoring data should be collected in accordance with this document and other relevant standards, guidelines and policies. The Queensland Government will not be held responsible for submission of incorrect data. The Queensland Government also reserves the right to use submitted monitoring data for any purpose it sees fit including supply of data to a third party.

Refer to Appendix C1 for further guidance and checklists of what information needs to be included when submitting electronic water monitoring data.

## Part C Appendixes

### Appendix C1 Forms

Examples of forms mentioned in the manual are provided here for use directly or as templates. They are:

- Sampling Schedule for Waters, Waste, Sediments
- Checklist of Equipment and Materials
- Analysis Request
- Chain of Custody Data Sheet
- Examples of Field Instrument Maintenance and Calibration Record Sheets.

SAMPLING SCHEDULE for Waters, Wastes, Sediments									
Sampler's Name:					Date:				
Activity or Investigation:									
Site	Sample Type: Waters, Wastes or Sediment	Tests	Container Code			Filling & filtering	Preservative	Storage Conditions	Rec. max. holding period
			V	W	M				

# Checklist of Equipment and Materials

Insert x if not required during trip; for remaining items, tick ✓ when packed.

[Modify as needed]

Item	x/✓
<b>For Personal Safety:</b>	
<i>Respiratory protection:</i> Face mask (suited to hazards expected)	
<i>Head protection:</i> Hat	
Safety helmet	
Sunscreen cream	
<i>Face protection:</i> Face Shield	
Safety Spectacles	
<i>Hand protection:</i> Gloves - disposable	
Gloves - heavy duty	
Hand-washing disinfectant cream	
Water for hand washing (if no access to suitable facilities)	
Ear muffs or ear plugs	
Safety boots	
Coveralls (disposable if required)	
<b>For Field Measurements:</b>	
Calibrated Thermometer	
Distilled water in wash bottle	
D.O. Meter	
D.O. probe, checked intact	
spare battery	
air calibration table	
manufacturer's instructions	
pH Meter	
electrode(s), checked intact	
buffer solutions	
small beaker (50 mL)	
spare battery or battery charger	
manufacturer's instructions	
Conductivity Meter	
electrode(s), checked intact	
calibration solution	
small beaker	
manufacturer's instructions	
<i>Chlorine test kit:</i> Comparator	
Comparator colour filters	
Moulded cells	
DPD No. 1 tablets	
DPD No. 2 tablets	
DPD No. 3 tablets	
Glass stirring rods	

Item	x/✓
<b>For Sample Collection and Preservation:</b>	
Sampling schedule	
Containers as per sampling schedule	
Preservatives as per sampling schedule	
pH test strips	
Sampling beaker or similar (if necessary)	
Sampling rod	
<i>Microbiological Sampling Kit:</i> Stainless steel sampling jug	
Gas torch for flaming inside of jug	
Igniter or matches	
<i>Vacuum Filtration Equipment:</i> Vacuum flask (1 Litre)	
Hand-operated vacuum pump	
Filter funnel with support screen	
Fine glass fibre filters	
Chlorophyll Sample Tubes	
Aluminium foil	
<i>Pressure Filtration Equipment:</i> Filtration syringe	
0.45 µm membrane filters	
Glass fibre pre-filters	
<b>For Sample Security and Transport:</b>	
Official seals for Samples	
Waterproof Marking Pens for labelling	
Waterproof transparent tape	
Insulated Carrier Boxes (coolers)	
Padlocks for Carrier Boxes (if used)	
Crushed Ice	
Dry Ice (or alternative)	
<b>For Recording Information:</b>	
Official Notebook	
Waterproof Ink pens (including spares)	
<i>Forms:</i> Analysis Request	
Notice of Samples Expected (if not already sent)	
Camera	
Spare film(s)	
Spare batteries	
<i>any accessories needed:</i>	
Tape recorder	
Spare tape cassette(s)	
Spare battery	

## Analysis Request

## Examples of Field Instrument Maintenance and Calibration Record Sheets

These are examples of record sheets suitable for storing chronologically in a ring file binder. They are provided here as a guide for designing record sheets specific to brands and models used by work units. For specific instruments, both the frequency of maintenance tasks and the appropriate calibration endpoints for recording should follow the manufacturer's recommendations.

### Maintenance Records

Example 1 – Preventative Maintenance Checklist

PREVENTATIVE MAINTENANCE CHECKLIST  
 YSI/GRANT MODEL 3800 WATER QUALITY LOGGER  
 METER NUMBER 703 DATE 15/10/99

GENERAL

Probes mounted in the sonde require routine maintenance to ensure accurate water quality measurements are available at all times. Refer to appendix 7 of the Water Quality Monitoring Quality Assurance Manual for details of maintenance procedures.

No	REQUIREMENT	STANDARD	ACTION	INITIALS
1	Battery Check	Replace if < 7.7 volts	8.1 V	
2	Clean Conductivity Probe	Weekly/as required	✓	
3	Clean DO probe	Weekly/as required	✓	
4	Replace DO probe membrane	Every 2 - 4 weeks/as required		
5	DO anode ammonia treatment	As required		
6	Clean pH probe	Weekly/as required	✓	
7	Recondition pH probe	As required		
8	Clean Temperature Probe	Weekly/as required	✓	
9	Clean Depth Probe	Weekly/as required	✓	
10	Reinitialise meter	Monthly	✓	
11	Recharacterise depth probe	Annually (by manufacturer)		

Example 2 – Preventative Maintenance Log Sheet

LOGSHEET METER NUMBER 903

DATE	ACTION/INCIDENT/FAULT	INITIALS
16/10/96	D.O. membrane displaced a bit in site of probe. Replaced	
16/10/96	Turbidity "0" recalibrated. Was reading 2 in 0	
23/10/96	Turbidity "0" recalibrated. Was reading 4 in 0	
7-1-97	Reinitialised ok	
6-1-97	At 0.58, the second point on pHV survey, meter function on pH 8.75 Temp 25.5	
	Looses V <sub>o</sub> . Jaws beam switch off and on. Unusable but last date.	
6-1-97	in. 4.5% problems - Reinitialised	
	time. DO still unstable.	
7-1-97	All OK - operated fine all day until last thing. 0.01% all probes. Reconnected cable from both ends to no avail.	

**Calibration Records**

## Appendix C2 Methods for overcoming limit of detection problems: in situ extractions and the use of passive samplers

The standard grab sample water bottle has a volume of 1 litre or less. However, this is an insufficient volume for the analysis of many contaminants at the sub-microgram per litre concentrations necessary for assessing compliance with water quality guidelines. In principle the level of detection could be improved by collecting a larger sample (e.g. a 10 litre volume could provide an order of magnitude improvement over a 1 litre volume) but this presents many practical difficulties of preservation, transportation, storage and extraction.

More practical options available include in situ extraction of the contaminants of interest, or the use of passive sampling devices.

In addition to resolving level of detection limitations, such techniques (especially passive sampling) provide a practical means of time-integrated sampling whereby contaminants can be monitored on a continuous basis for extended periods (up to several weeks at a time).

These sampling techniques provide an additional set of tools useful for modern monitoring programs.

### C2.1 In situ extraction

One such system, solid phase extraction (SPE), makes use of the tendency of contaminants with low water solubility to bind to specific solid materials.

The main advantage of in situ concentration is that large amounts of water can be extracted in the field and need not be transported. In addition, because these systems can be deployed for long periods, they can provide a relatively inexpensive method for integration of contaminants over time. The basic elements for such a system (piping, filter/s, sorbent column/s, pump, power supply, flow meter, control system) can be assembled readily by a good laboratory workshop. Such a system is illustrated in Figure C1.

Figure C1 An in situ sampling system pumps a measured volume of water through a sorbent cartridge

Due to the risk of contamination during field extraction of water samples using SPE, it is highly desirable to avoid contact between the water being sampled and the mechanical components of the pump prior to the water reaching the solid phase. Generally, this necessitates plumbing the pump so that it sucks rather than drives water through the extracting media. In practice this requires that the sampling device be situated as close as practical to the level of the water source because suction is limited to one atmosphere of negative pressure, and in practice, due to inherent resistances in the system (piping, filter/s and extracting media), 1–2 m altitude difference is the maximum achievable.

The risk of introducing contaminants from tubing and other components of an in situ sampler is similar to that inherent in automatic samplers (see section 3.1.2). Other requirements of QA/QC also apply such as the wearing of gloves to avoid contamination of sampler components that come in contact with the sample.

## **C2.2 Passive sampling devices**

In principle the use of a passive sampling device involves the deployment of a chemical-absorbing material in the water column (or sediments). After a period of exposure, the absorbent material is retrieved and the accumulated chemicals analysed. Passive samplers can be used to detect contaminants and also to estimate average exposure concentrations during the period of deployment. The latter can be calculated from the duration of exposure, the measured concentration of contaminant accumulated, and the absorption rate of the material used in the sampler.

The basic components of a passive sampling device are an accumulating medium, a membrane to control the rate of uptake, and a mounting structure to contain and protect these components but at the same time expose them to the water being sampled.

Passive sampling devices can be deployed in the field in a variety of situations—hung from floats, suspended from jetties, fastened to stakes inserted in a stream bottom, or anchored to the bottom but held up into the water column by a float.

The normal requirements of QA/QC apply when sampling with passive sampling devices. These include the use of field blanks, replicate samplers, and precautions such as the wearing of gloves to avoid contamination of the sampler or its housing during handling.

Time-integrating passive sampling techniques have become widely used in the last decade. In particular, the use of performance reference compounds introduced into the sampler to enable adjustment of field data from the samplers using kinetic data from the laboratory has increased user confidence in these sampling techniques.

A variety of accumulating media for passive sampling are available, allowing a choice based on the chemical properties of the target contaminants. Examples of common types are as follows.

### **C2.2.1 Passive sampling for organic pollutants**

#### **C2.2.1.1 Semi-permeable membrane device**

The most widely used passive sampler design for non-polar chemicals in water is the semi-permeable membrane device (SPMD) shown in Figure C2. It consists of a length of sealed lay-flat PE tubing (the membrane) containing a small volume of triolein (the absorbent phase) woven around a stainless steel frame. The device is then inserted into a perforated stainless steel shroud for protection from mechanical damage during deployment.

Trace levels of contaminants that cannot be detected in conventional water samples are often concentrated to detectable levels by SPMDs or similar devices placed in water for a controlled exposure period.

An alternative to the triolein-based SPMD described above is to use a strip of silicon rubber such as polydimethylsiloxane (PDMS) placed inside the deployment shroud as the absorbent material.

**Figure C2 Housing and components of an SPMD passive sampler. The protective cage covers the absorbent strip during deployment**

### C2.2.1.2 Chemcatcher

This device is a very robust passive sampling device that employs the C18 Empore disk as the absorbent media, combined in most cases with a membrane that allows diffusion of polar chemicals. Depending on the polarity range of the analytes of interest, a range of devices incorporating appropriate membranes and solid phase absorbent media have been developed. One of these devices based on the Empore disk is illustrated in Figure C3.

**Figure C3 Housing and components of a Chemcatcher passive sampling device**

The sampler consists of three interlocking sections (2, 3, 9) manufactured from polytetrafluoroethylene (PTFE) that screw together during deployment to form water-tight seals (4, 10).

Integral to the device is a 50 mm rigid PTFE disk (7) designed to support both the absorbent material (Empore) (5) and the diffusion-limiting membrane (6).

On the reverse is a lug (1) for attaching the device during deployment.

The outer surface of the diffusion-limiting membrane is protected from mechanical damage during deployment by a mesh (8) of either stainless steel for organic analytes or nylon for inorganic analytes. This mesh is held in place during deployment by a removable PTFE ring (9).

A PTFE screw cap (11) replaces the ring (9) during transport to and from the deployment site.

### C2.2.2 Passive sampling for metals

The diffusive gradient in thin film (DGT) device employs a resin gel as the accumulating absorbent media, overlaid by a filter (to exclude particulates) and a diffusive hydrogel to maintain a concentration gradient, with the whole loaded into a cylindrical plastic housing (see Figure C4). A series of different gels have been developed to sample a range of metals (both labile and organic species), phosphorus, sulphides and radioactive caesium, and are available in a range of thicknesses. Parallel deployment of two DGT units assembled with different diffusive gel thicknesses allows accurate measurement under low flow conditions.

An important advantage of using DGT to measure metals in saline or marine waters is that the gels do not accumulate the major ions that often cause interferences in the analysis of metals in grab samples of water. The devices sample satisfactorily over a range of pH, with the range limits varying between metals (e.g. down to pH 2 for Cu, but only 4.5 for Cd) and over the range pH 2 to 9 for phosphate.

A variant of the device, known as DET (diffusive equilibrium in thin films) can be deployed to perform relatively rapid (within a day) response times and has the ability to measure at high spatial resolution. The DET comprises a single relatively thick sheet of gel (typically 0.8 mm) supported in a holder. Solutes in the surrounding water diffuse into the gel until concentrations in gel and water are equal.

DGT and DET devices, for both of which the University of Lancaster (UK) holds a worldwide patent, are available commercially, either pre-assembled or in kit form (gel disks and strips for local assembly). For details of supply visit the DGT for measurements in waters, soils and sediments website at <[www.dgtresearch.com](http://www.dgtresearch.com)>.

Figure C4 Housing and components of a DGT passive sampling device

## Appendix C3 Flow measurement

The most relevant Australian standard for flow measurement of water bodies is AS 3778, parts 1 to 6—Measurement of water flow in open channels. This standard is also relevant to some types of flow measurement for point source discharges. The standard describes comprehensively the range of available methods for measurement. For wastewater discharges, AS 2360—Measurement of fluid flow in closed conduits may also be relevant. Important aspects of these two standards are discussed briefly below.

Methods for measuring water flow in open channels are mainly divided into velocity-area method, measuring structures, dilution method, slope-area method and cubature method. AS 3778.21 (2001) provides guidance on selecting the appropriate methods and explains uncertainties associated with each method.

Velocity-area methods are described in detail in AS 3778 (Part 3). The velocity-area methods are commonly used for estuaries and freshwater streams where no physical measuring structures exist. Some of the methods can also be adopted for measuring wastewater flow in open channels. Most common methods for instantaneous measurements include using velocity meters (stationary or on a boat) and timing a float travelling over a known distance (freshwater only). Continuous measurements can be made using ultrasonic (velocity of sound in water) meters and electromagnetic induction in buried coils.

Weirs, flumes or other physical structure work on the principle that volumetric flow rate is related to a known cross-sectional area or height before some fall. This type of method is often used for freshwater gauging stations and can be used for measuring wastewater flow in an open channel. Some type of water measuring device that needs to be calibrated is usually required for continuous measurement.

The dilution method involves the use of a tracer and sampling of waters to measure the concentration of the tracer where it has uniformly mixed across the cross-section of the waterway. This method of flow measurement is only applicable to freshwater streams. However, tracers are commonly used in estuarine and marine waters to study the dispersion of a wastewater release and to calibrate the hydrodynamics of water quality models.

Methods for measuring flow in closed conduits such as pipes are mainly divided into pressure differential methods, mass methods and volumetric methods. Calibration is essential for this method and strongly linked to the uncertainty of the measurement (see AS 2360.7.1/AS 2360.7.2).

Pressure differential methods are commonly used for measuring flow into plants such as sewage treatment plants and may be used to infer the discharge quantities where flow losses are minimal. Confidence in the flow measurement is strongly dependent on appropriate calibration and should be undertaken as per AS 2360.7.1.

The main types of volumetric methods include static and dynamic gauges, diverters and flow stabilisers. The most common volumetric method used for wastewater discharges is a flow stabiliser where a device such as a pump is used to ensure a stable flow-rate is supplied. If the flow is not continuous, the duration for which the water is flowing can be recorded to calculate total flow for a known period.

Regardless of the method used, it is important that overall uncertainty in the flow measurement is known or calculated. Refer to AS 3778.2.4 for estimation of uncertainty of a flow-rate measurement in open channels and AS 2360.7.1 and AS 2360.7.2 for assessment of uncertainty in calibration and use of flow measurement devices for closed conduits and the specific subsections of AS 2360 for the method adopted.

## Appendix C4 Sampling water quality in temporary waters

Temporary waters predominantly occur within arid and semi-arid regions in Australia and are by nature highly variable systems. Temporary waters include:

- **intermittent waters:** areas that are predictably inundated each year, but whose duration of water retention may vary
- **ephemeral waters:** areas that only contain water after irregular rainfall or flow events.

Before any sampling of temporary waters begins, thorough consideration should be given to all the environmental and discharge factors presented below. Regional departmental officers are advised to consult with the Queensland Department of Environment and Resource Management Environmental Sciences division while others are urged to seek advice from environmental consultants experienced in developing sampling programs for temporary waters.

### C4.1 Sampling the receiving environment

Due to the highly variable nature of receiving environments in arid and semi-arid areas, there is no standard set of sampling techniques. Choosing the correct approach will depend on a variety of factors, which include the:

- stage of the hydrocycle (flowing, pooling or dry)
- amount of vegetation in the catchment
- underlying geology of the waterways
- amount of biological activity
- location along the catchment (sink, shallow flowing, etc.)
- proximity of sensitive areas or areas of special significance
- variations in the intensity of evapo-concentration
- accessibility to potential sampling locations.

Ideally, there should be a temporal as well as a spatial component to the sampling of temporary waters. Sampling should be distributed evenly along the catchment and through time to get a clear indication of water quality.

### C4.2 Sampling release waters

Certain considerations need to be taken when sampling temporary water receiving environments after a discharge or release has occurred. Due to the temporary nature of the flow in these water bodies, there is the potential for environmental harm to occur:

- with the resumption of flow, where active ecosystems located downstream of the discharge point are subjected to a pulse exposure to contaminants
- with the cessation of flow, where the concentration of contaminants within remnant pools begins to increase due to the effects of evapo-concentration.

Historical releases during dry phases may have resulted in the accumulation of contaminants in the sediments. With the resumption of flow (either due to rainfall, wastewater release or other cause), these contaminants can be remobilised and may cause environmental harm to ecosystems located downstream. The level of environmental harm (if any) is dependent on the concentration of the contaminants and the level of dilution afforded by the flow. This is discussed in greater detail in section C4.3.1 below.

Sampling of temporary waters at or downstream of the release point should always be accompanied by reference site sampling. Additionally, wherever possible, sampling should take place at multiple points within both the receiving and the reference environments so that suspect or outlier data can be recognised.

### **C4.3 What to sample**

There are three main approaches to establishing water quality in temporary waters, namely:

- surface waters
- sediment
- biological assessment.

A brief outline of each of these approaches is presented below. Further guidance to each of these can be found in ANZECC/ARMCANZ (2000).

#### **C4.3.1 Surface waters**

The sampling of temporary waters is usually event-based, occurring upon resumption of rainfall during the flood stage of the hydrocycle or release/overflow of waters from an industry. It may take the form of manual grab samples of surface waters, or be performed by remote automatic samplers that trigger sampling at a particular water level or at pre-determined intervals. To ensure adequate monitoring of contaminants, water samples should also be collected as the drying phase of the hydrocycle progresses. Protecting the ecosystem in temporary waters is usually easier during high flow events due to the effects of dilution. However, when flow diminishes, evapo-concentration of contaminants in surface waters can occur, thereby potentially heightening the effects of exposure on components of the ecosystem. It is during the drying phase that many of the ecosystem components are in their reproductive stages. Even in the 'dry' state there is an array of live organisms in the sediments, often in desiccation-resistant life stages ready to repopulate the surface waters when the waters return.

It is recommended that the Queensland AusRivAS methodology be adopted when sampling non-permanent waterways (see section 4.1).

It should be noted that the initial flush of water after dry periods will be very likely to give a skewed assessment of water quality. The first flush that occurs immediately after rainfall may be more damaging (poorer water quality) than the subsequent flow; however, this pulse is typically only short lived and is unlikely to harm encysted or dormant stream fauna.

There are two scenarios that are likely to be encountered where temporary waters exist. If the receiving environment is:

- an ephemeral or temporary waterway without pools, or temporary or permanent water bodies of ecological significance for many kilometres downstream, any live biota still existing within the boundaries of the watercourse will most likely be in a dormant stage below the sediment surface. Consequently, there will be minimal exposure to the first flush of water that enters that watercourse. Hence sampling of remnant water that will harbour and support the emergent biota will be much more ecologically relevant
- an ephemeral or temporary waterway with pools, or temporary or permanent water bodies of ecological significance located downstream, and is likely to be impacted by first flush water flows, permanent or recently established water bodies will most likely harbour active life stages of biota. These will be vulnerable to the effects of a pulse exposure of contaminants associated with first flush waters. In this case, sampling of the first flush water and sampling of the residing water in the permanent/semi-permanent water body (post-exposure) would be warranted.

Due to the variability in flows, it can be useful to incorporate automatic samplers for sampling temporary waters. See section 3.1.2 on using automatic samplers.

#### **C4.3.2 Sediments**

Water quality should be measured directly and quantified wherever possible; however, this is seldom possible in arid environments. It is more likely that samples will need to be taken during the dry stage of the hydrocycle. Sampling may have to rely partially or entirely on historical deposition of contaminants in the sediment of dry river beds.

Contaminants in sediment samples can be extracted in the laboratory to estimate their potential bioavailability.

Some of the problems inherent in relying on sediment quality are that:

- the relationship of sediment quality to actual water quality is often uncertain, making extrapolation of data difficult
- only sediment bound contaminants will be measured
- sediment is typically heterogeneous and so care must be taken in ensuring appropriate replication and/or composite sampling.

For further sampling information, refer to AS/NZS 5667.12:1999 Guidance on Sampling Bottom Sediments.

#### **C4.3.3 Biological assessment**

Biological assessment can be a valuable way to establish changes in water quality. This usually involves long-term monitoring of assemblages of organisms both at the impacted and reference sites. Biological monitoring can give an early indication of reduction in water quality.

Guidance on selecting the best approach and the associated methodologies of each can be found in Section 8.1 of ANZECC/ARMCANZ (2000). Some of the approaches to biological assessment are:

- direct toxicity assessment
- seed propagule banks
- aquatic plants (algae and macrophytes)
- monitoring of hyporheic and epigeal fauna.

Some of these biological approaches may require specialist localised knowledge of taxa, and assistance from the appropriate experts may be difficult to procure.

For further guidance, Smith et al (2004) have produced a valuable review of the benefits and flaws inherent in various sampling methodologies in evaluating the impacts of mining in arid and semi-arid regions of Australia.

Further information on applying the ANZECC/ARMCANZ (2000) guidelines to sampling results for temporary waters have been addressed in Batley et al (2003), A Guide to the Application of ANZECC/ARMCANZ Water Quality Guidelines in the Minerals Industry. This publication also provides some extra advice on sampling strategies for temporary waters.

## Appendix C5 Bulk natural water and sediment collection for direct toxicity assessment (DTA)

Direct toxicity assessment (DTA) is a useful tool for characterising the combined toxicity of contaminants in a mixture. The toxicological effects of chemicals in combination can be quite different from the effect of each chemical in isolation. By comparing DTA results with the actual or estimated load of contaminants in a discharge, it is possible to develop a range of predictive conditions and potential effects on biota for specific discharge events.

A limitation of DTAs is that it may be difficult to obtain test species that are ecologically relevant (i.e. present) in the catchment being sampled. In such cases, the relevance of DTA results to field situations may be limited due to different sensitivity between species. Nonetheless, the relative toxicity of the discharge to 'standard test organisms' can still be very useful in quantifying the environmental risk posed by the activity.

DTAs can be conducted on bulk water samples or extracts from sediments. Contact the analyst to obtain detailed advice on how to collect samples for DTA before collection.

When collecting bulk receiving environment water samples for the purpose of diluting effluent to be used in DTAs, collect the appropriate volume of water according to the testing laboratory's advice, which should include:

- bottle type
- field storage requirements
- instruction on any preservatives to be used
- instruction on sample security
- instructions for transport.

If the required information is unobtainable prior to collection, follow the guidance provided in this manual.

It is a requirement that physicochemical parameters (pH, conductivity, temperature, ammonia, dissolved oxygen, turbidity and suspended solids) be measured (in the field wherever possible) at the time of collection in accordance with the instructions in this manual, and then again prior to conducting any dilution of the effluent to be tested for the DTA. There may be a requirement for additional parameters to be tested both in the field and prior to using the collected water for effluent dilutions where the time for transport and use of the receiving environment water in the bioassays exceeds 24 hours. Seek advice on this from the department (who will assess this requirement on a case-by-case basis).

Further information on the use of DTA in water quality assessment can also be found in the review by Smith et al (2004), and in the ANZECC/ARMCANZZ (2000) Australian and New Zealand Guidelines for Fresh and Marine Water Quality.

## Appendix C7 Units and concentrations

When taking readings from field instruments and test kits, and in interpreting data from sample analysis relative to guideline thresholds and limits in licences and permits, a variety of equivalent and non-equivalent units may be encountered. Take care with units and be consistent in recording readings and interpreting data. To reduce the risk of errors, using standard units of measurement is preferable to generic terms such as 'parts per million'.

Concentrations may be written in symbols using a variety of forms, for example milligrams per litre as  $\mu\text{g/L}$  or as  $\mu\text{g.L}^{-1}$  both of which are equivalent.

### Standard units and their abbreviations

Kilogram	kg	$10^3$	Parts per thousand	g/kg	mg/g	g/L	mg/mL	$\mu\text{g}/\mu\text{L}$	
Gram	g	1	Parts per million	ppm	mg/kg	$\mu\text{g}/\text{g}$	mg/L	$\mu\text{g}/\text{mL}$	ng/ $\mu\text{L}$
Milligram	mg	$10^{-3}$	Parts per billion	ppb	$\mu\text{g}/\text{kg}$	ng/g	$\mu\text{g}/\text{L}$	ng/mL	pg/ $\mu\text{L}$
Microgram	$\mu\text{g}$	$10^{-6}$	Parts per trillion	ppt	ng/kg	pg/g	ng/L	pg/mL	fg/ $\mu\text{L}$
Nanogram	ng	$10^{-9}$	Parts per quadrillion	ppq	pg/kg	fg/g	pg/L	fg/mL	ag/ $\mu\text{L}$
Picogram	pg	$10^{-12}$							
Femtogram	fg	$10^{-15}$							
Attogram	ag	$10^{-18}$							

Note particularly that units used to express results by field instruments and test kits are not necessarily consistent with those used in compliance requirements or guideline documents, e.g. phosphate as phosphate ( $\text{PO}_4$ ) is not the same as phosphate as phosphorus (P), similarly, nitrate as nitrate ( $\text{NO}_3$ ) is not the same as nitrate as nitrogen (N), and ammonia as ammonium ( $\text{NH}_4$ ) is not the same as ammonia as nitrogen (N). Use the conversion factors listed below.

**Conversion factors for concentrations of N and P compounds**

1 mg/L of nitrate (NO<sub>3</sub>) as nitrogen (N) = 4.43 mg/L of nitrate as nitrate.

**To convert:**      mg(N)/L to mg(nitrate)/L      multiply by 4.43  
                          mg(nitrate)/L to mg(N)/L      divide by 4.43

1 mg/L of nitrite (NO<sub>2</sub>) as nitrogen (N) = 3.29 mg/L of nitrite as nitrite

**To convert:**      mg(N)/L to mg(nitrite)/L      multiply by 3.29  
                          mg(nitrite)/L to mg(N)/L      divide by 3.29

1 mg/L of ammonia (NH<sub>3</sub>) as nitrogen (N) = 1.21 mg/L of ammonia as ammonia

**To convert:**      mg(N)/L to mg(ammonia)/L      multiply by 1.21  
                          mg(ammonia)/L to mg(N)/L      divide by 1.21

1 mg/L of ammonium (NH<sub>4</sub>) as nitrogen (N) = 1.29 mg/L of ammonium as ammonium

**To convert:**      mg(N)/L to mg(ammonium)/L      multiply by 1.29  
                          mg(ammonium)/L to mg(N)/L      divide by 1.29

1 mg/L of phosphate (PO<sub>4</sub>) as phosphorus (P) = 3.066 mg/L of phosphate as phosphate

**To convert:**      mg(P)/L to mg(ammonium)/L      multiply by 3.066  
                          mg(ammonium)/L to mg(P)/L      divide by 3.066

**Molar units and their abbreviations**

Concentrations may also be expressed in molar units (M). A mole is  $6.022 \times 10^{23}$  particles (of nitrogen, or ammonia, or phosphorus, etc.). A mole of anything contains the same number of items.

A molar concentration is the number of moles in a litre of solution, for example, a 1M solution of ammonia as nitrogen (N) contains 14 grams of nitrogen (N) in a litre of solution (14 gN/L).

Using the standard units table above it follows that a 1 mM solution of ammonia contains 0.014 gN/L, and a 1  $\mu$ M solution of ammonia contains 0.014 mgN/L.

**Conversion factors for concentrations in molar units**

**Ammonia – N and Nitrate – N and Nitrite – N**

1M ammonia (or nitrate or nitrite) as nitrogen (N) = 14 gN/L,  
therefore 1.0 mgN/L ammonia (or nitrate or nitrite) = 71.4  $\mu$ M

**To convert:**      mgN/L to  $\mu$ M      multiply by 71.4  
                          $\mu$ M to mgN/L      divide by 71.4

**Urea – N**

1M urea as nitrogen (N) = 28 gN/L,  
therefore 1.0 mgN/L = 35.7  $\mu$ M

**To convert:**      mgN/L to  $\mu$ M      multiply by 35.7  
                          $\mu$ M to mgN/L      divide by 35.7

**Phosphate – P**

1M phosphate as phosphorus (P) = 31 gP/L,  
therefore 1.0 mgP/L = 32.3  $\mu$ M

**To convert:**      mgP/L to  $\mu$ M      multiply by 32.3  
                          $\mu$ M to mgP/L      divide by 32.3

**Silicon – Si and SiO<sub>2</sub>**

**To convert:**      SiO<sub>2</sub> to Si      multiply by 0.4674

1M silica (Si) = 28.1 gSi/L,  
therefore 1.0 mgSi/L = 35.6  $\mu$ M

**To convert:**      mgSi/L to  $\mu$ M      multiply by 35.6  
                          $\mu$ M to mgN/L      divide by 35.6

**Conductivity units and their abbreviations**

The unit of measurement for conductivity is siemens (S) per unit of length. A siemen is the reciprocal of the unit of electrical resistance, the ohm ( $\Omega$ ).

Some common EC unit expressions used for reporting conductivity are:

- microsiemens per centimetre ( $\mu\text{S}/\text{cm}$  or  $\mu\text{S}\cdot\text{cm}^{-1}$ )
- millisiemens per centimetre ( $\text{mS}/\text{cm}$  or  $\text{mS}\cdot\text{cm}^{-1}$ )
- decisiemens per metre ( $\text{dS}/\text{m}$  or  $\text{dS}\cdot\text{m}^{-1}$ )
- millisiemens per metre ( $\text{mS}/\text{m}$  or  $\text{mS}\cdot\text{m}^{-1}$ ).

The SI unit is  $\text{mS}/\text{m}$ . Equivalence relationships among these units include:

- $1 \text{ dS}/\text{m} = 1 \text{ mS}/\text{cm} = 100 \text{ mS}/\text{m} = 1000 \mu\text{S}/\text{cm}$
- $1 \text{ mS}/\text{m} = 10 \mu\text{S}/\text{cm}$

## Appendix C8 Sample containers and preservation methods

**IMPORTANT:** Use section 3.3 to interpret these tables correctly.

Table C8.1 Alphabetic list of water quality characteristics covered in this manual

Parameter	Quick reference
Acidity and alkalinity	
Adsorbable organic halide (AOX)	
Aluminium	See 'metals'
Ammonia	See 'nutrients'
Anionic surfactants	See 'surfactants, anionic'
Arsenic	See 'metals'
Barium	See 'metals'
Biochemical oxygen demand (BOD)	
Boron	
Bromide	
Cadmium	See 'metals'
Calcium	See 'metals'
Chemical oxygen demand (cod)	
Chloride	
Chlorine, free	
Chlorine, free residual	See 'chlorine, free'
Chlorine, total	
Chlorophylls	
Chromium	See 'metals': separate entries for 'hexavalent' and 'total' forms
Cobalt	See 'metals'
Colour	
Conductivity	
Copper	See 'metals'
Cyanide	
Dissolved oxygen	
Electrical conductivity	See 'conductivity'
<i>Enterococci</i>	See 'bacteria'

Parameter	Quick reference
<i>Escherichia coli</i> and thermotolerant coliforms	See 'bacteria'
Faecal coliforms	This term has been superseded by 'thermotolerant coliforms'
Fluoride	
Hardness	See 'metals'—'calcium', and follow instructions under that heading
Herbicides	See 'herbicides and pesticides'
Hydrocarbons, petroleum	
Iodide	
Iron	See 'metals'
Lead	See 'metals'
Lignins and tannins	
Magnesium	See 'metals'
Manganese	See 'metals'
Mercury	See 'metals'
Molybdenum	See 'metals'
Nickel	See 'metals'
Nitrate	See 'nutrients'
Nitrite	See 'nutrients'
Nitrogen, oxidised	See 'nutrients': 'oxidised nitrogen' is the sum of nitrate and nitrite
Nitrogen, total	See 'nutrients'
Nitrogen, total kjeldahl	See 'nutrients'
Non-ionic surfactants	See 'surfactants, non-ionic'
Oil and grease	
Organotins (e.g. TBT)	
Oxygen, dissolved	See 'dissolved oxygen'
Pesticides	See 'herbicides and pesticides'
pH value	
Phosphorus, dissolved	See 'nutrients'
Phosphorus, total	See 'nutrients'
Polychlorinated biphenyls (PCB)	

Parameter	Quick reference
Polynuclear aromatic hydrocarbons (PAH)	
Potassium	See 'metals'
Selenium	See 'metals'
Silver	See 'metals'
Sodium	See 'metals'
Solids, dissolved	
Solids, suspended	
Sulphate	
Sulphide	
Surfactants, anionic	
Surfactants, non-ionic	
Suspended solids	See 'solids, suspended'
Thermotolerant coliforms	See 'bacteria'
Total dissolved solids	See 'solids, dissolved'
Trihalomethanes and haloacetic acids	
Turbidity	
Uranium	See 'metals'
Vanadium	See 'metals'
Zinc	See 'metals'

When a parameter is not identified in this manual, contact the analyst for proper collection techniques.

**Table C8.2 Water samples—containers and preservation methods**

Quality characteristic (water samples)	Container code (as above)			Filling method and/or sample filtering (if any)	Preservative to add [†]	How much: (a) OR (b)		Storage conditions [§]	Rec. max. holding period [†]	Other instructions
	V	W	M			(a) Mass or volume	(b) to pH shown			
Acid t y and a ka n t y	250	D	P	F containing excude ar	None	—	—	Refrigerate	24 hours	Analyse in the field if practicable (consult analyst about procedure)
Adsorbab e organ c ha de (AOX)	1000	A	G	F containing excude ar	Nitric acid	—	1-2	Refrigerate in the dark	3 days	Transport sample promptly to laboratory so that analysis can be started as soon as practicable
Bacter a <i>Escherichia coli</i> and thermotolerant bacter a Enterococ	200	See note [2]	G or P	—	—	—	—	Refrigerate	Maximum 24 hours see note [3]	—
Biochem ca oxygen demand (BOD)	1000	W	G or P	F containing excude ar	None	—	—	Refrigerate in the dark	24 hours	Check with the laboratory on suitable arrival time
Boron	100	D	P	F containing excude ar	None	—	—	—	1 month	—
Bromide	100	D	P	—	None	—	—	Refrigerate in the dark	1 month	—
Chem ca oxygen demand (COD) (use 1 of the 2 methods)	100	A	G or P	F containing excude ar	Sulphuric acid	—	1-2	Refrigerate	7 days	—
Chem ca oxygen demand (COD) (use 1 of the 2 methods) Method 1	100	A	G or P	F containing excude ar	Sulphuric acid	—	1-2	Freeze	1 month	—
Chem ca oxygen demand (COD) (use 1 of the 2 methods) Method 2	100	A	G or P	F containing excude ar	Sulphuric acid	—	1-2	Freeze	1 month	—

Container codes: V, Volume: Typical sample volume, mL (see note [1]); W, Washing: A = Acid, D = Detergent, S = Solvent, W = Water, M, Material: G = Borosilicate Glass, P = Plastic (examples: Polyethylene, PTFE, PET, polypropylene or similar); [†] Except where specifically stated otherwise, put sample in container first, THEN add the preservative/s. [§] Refrigerate = cool to 1-4°C; Freeze = freeze to -20°C; [†] Denotes recommended maximum time from collection in the field to analysis in the laboratory.

Chloride	100	D	P	—	None	—	—	—	—	Keep sample out of direct sunlight	1 month	—
Chloride, free	100	D	P	—	None	—	—	—	—	Keep sample out of direct sunlight	5 min	Determine immediately on site
Chloride, total	100	D	P	—	None	—	—	—	—	Keep sample out of direct sunlight	5 min	Determine immediately on site
Chlorophyll (use 1 of the 2 methods)	See note [4]	—	—	See note [4]—keep filter paper (filtered quds not required for tests)	None	—	—	—	—	Refrigerate in the dark	24 hours	Sample must be transported in the dark
Chlorophyll (use 1 of the 2 methods)	1000	D	G or P	—	—	—	—	—	—	Wrap to defend filter paper in a um in um fo and freeze in the dark	1 month	—
Cobalt	500	D	P	—	None	—	—	—	—	Refrigerate in the dark	48 hours	—
Conductivity (use 1 of the 2 methods)	100	W	P	F container completely to exclude air	None	—	—	—	—	Refrigerate	24 hours	Determine in situ or on site if possible
Conductivity (use 1 of the 2 methods)	100	W	P	F container completely to exclude air	None	—	—	—	—	Refrigerate	1 month	—
Cyanide, Total see note [5]	500	W	P	—	Sodium hydroxide solution (see caution*)	—	=>12	—	—	Refrigerate in the dark	24 hours	*Caution: this procedure can create etha HCN gas
Dissolved oxygen (DO) (use 1 of the 2 methods)	300	W	G	—	None	—	—	—	—	—	—	Determine in situ or on site
Dissolved oxygen (DO) (use 1 of the 2 methods)	300	W	G	—	Winkler solution	—	—	—	—	Store in the dark	24 hours	—
Furide	200	D	P	—	None	—	—	—	—	—	1 month	PTFE (poly-tetrafluoroethylene) containers are unsuitable
Herbicides and pesticides:	1000	S	G*	Do not pre-rinse container with sample material. Do not completely fill container (leave headspace of approx. 1-2 cm depth)	Sodium thiophosphate; see note [6]	—	—	—	—	Refrigerate in the dark	7 days	* Lid of sample container must have insert of a um in um or PTFE (poly-tetrafluoroethylene). Protect sample from light

Herbicides and pesticides: Carbamates pyrethrins synthetic pyrethroids organophosphorus and inorganophosphorus and pesticides	1000	S	G*	Do not pre-rinse container with sample material. Do not completely fill sample container (leave headspace of approx. 1-2 cm depth)	Sodium phosphate: see note [6]	80 mg per sample	—	Refrigerate	7 days	* Lid of sample container must have insert of aluminum or PTFE (polytetrafluoroethylene)
Hydrocarbons, petroleum	1000	S	G	Do not pre-rinse container with sample material. Fill bottle completely with sample (no headspace)	Sulfuric acid	—	1-2	Refrigerate	1 month	—
Iodine	500	D	P	—	None	—	—	Refrigerate in the dark	1 month	—
Lignins and tannins	250	W	G	—	None	—	—	Refrigerate	7 days	—
Metals —calcium or magnesium (use 1 of the 2 methods)	250	A	P	Fill container completely to exclude air	Nitric acid	—	1-2	—	1 month	—
Metals Method 1	250	A	P	Fill container completely to exclude air	None; see note [7]	—	—	—	7 days	—
Metals —chromium, hexavalent (see note [8])	100	A	P	—	None	—	—	Refrigerate	24 hours	—

Metals —mercury	250	A	G	For 'd sso ved' form, f ter on site; see note [9]	N tr c ac d and Potass um d chromate 50 mg/mL	— 5 mL per 250 mL sample; or more. (See right-hand column)	1-2	—	1 month	If sample wastes or contaminated waters, more potassium dichromate may be needed: • If sample is nitrate or a pale color, add 5 mL of preservative shoud turn the distillate over. If the color appears but then fades, more preservative is needed; so add a further 5 mL. Repeat if necessary. • If sample is nitrate or a dark color, it may be difficult to determine whether enough preservative has been added. Discuss with the analyst before sampling for practical reasons. Both preservation steps are required
Metals —potassium or sodium (use 1 of the 2 methods)	100	W	P	—	None	—	—	—	1 month	—
Metals Method 1 —potassium or sodium (use 1 of the 2 methods)	250	A	P		N tr c ac d	—	1-2	—	1 month	Permits measurement with other metals
Metals Method 2 —others: Aluminum, arsenic, barium, cadmium, chromium—total (hexavalent + trivalent), cobalt, copper, iron, lead, manganese, molybdenum, nickel, selenium, silver, uranium see note [8]	250	A	P	For 'd sso ved' form, f ter on site; see note [9]	N tr c ac d	—	1-2	—	1 month	—

METHOD 1											
Total organic carbon (TOC); see note [12] (use 1 of the 2 methods)	Ziplock plastic bag			—	None	—	—	Freeze	—	1 month	—
METHOD 2											

Note [1] The volume shown is a typical volume for a single determination. The actual volume needed depends on many factors. If practicable, discuss with the analytical laboratory before sampling.

Note [2] Sterilisers are required as specified in AS/NZS 2031 2001. For samples from chlorinated sources, these must contain sodium hypochlorite before sampling. The concentration must be such as to produce a concentration of at least 100 mg/mL in the sample. Where bottles are prepared by the laboratory, they should be supplied ready containing the required amount of sodium hypochlorite. Sodium hypochlorite neutralises chlorine, thus preventing further bacterial effects on organisms in the water during transport.

Note [3] AS/NZS 2031 2001 indicates that incubation should commence within six hours of collection; under exceptional circumstances this may be extended to a maximum of 24 hours. The analyst should attach a note to the test report stating the time interval between sample collection and testing.

Note [4] Filter the sample and submit the filter paper (along with the particulate matter accumulated on it) to the analyst. Filter the sample in the field using vacuum filtration equipment. Filter the sample through a fine glass fibre filter (Whatman GF/C or equivalent). The vacuum applied across the filter should be no more than 40 cm of mercury, to avoid possible rupture of cells and consequent release of chlorophyll. The volume of sample needed will depend on the concentration of particulate matter present; a typical volume to filter is 1000 mL, but for samples with high loads, the filter can become clogged before the volume has passed through. **You must record the volume that has actually passed through the filter, and give this information to the analyst with the sample.** Filters and collected particulates must not be touched with fingers and a sampling hand rig apparatus must be kept free of acids as this causes degradation of chlorophyll. Place filter paper in a container that excludes light (for example, a small tube completely wrapped in a non-reflective material) for transport to the analyst.

Note [5] When requesting analysis, specify which form you require to be determined.

Note [6] Preservative is needed on your sample especially chlorinated. Preservative should be in the bottle prior to filtering with sample.

Note [7] Second method (no preservative) can be used on your sample if: [a] pH = < 8 and low carbonate content; and [b] drawn solely for determination of calcium, magnesium or hardness.

Note [8] When collecting a sample for determination of chromium (VI), it is suggested that you also collect a sample for determination of total chromium and submit both for analysis. This allows the laboratory to perform the standard test for total chromium first; then, if none is detected, it need not carry out the more complex test for hexavalent (VI) chromium.

Note [9] Filter sample in the field, through 0.45 µm polyethersulfone filter, preferably using fully enclosed pressure filtering equipment, such as syringe (50 mL) with 0.45 µm syringe filter. For turbid samples a glass fibre pre-filter should also be used to make filtering easier.

Note [10] Containers to be methanated according with AS 5667.1:1998.

Note [11] You must specify which metals are to be determined in the sample.

Note [12] If analyses required for total organic carbon (TOC) as well as for pesticides and herbicides, the same sample will suffice for both analyses.

## Appendix C9 Fluvial sediment sampling using P 61 sediment samplers and Helley–Smith bedload samplers

### C9.1 Skills/competency and experience

Staff skills, training and experience records should be kept up to date. Skills/competency ideal for this method include:

- all members of the sampling party having a current Senior First Aid certificate
- at least one member of the sampling party having had previous training and experience in the use of this method.

During sampling, not all samples retrieved are acceptable. For example, water samples that are contaminated with bedload must not be sent for suspended sediment analysis as they are not representative. Therefore, experimentation may be required to get an idea of the stream condition before taking samples. The whole sampling exercise demands skill, experience and patience and it is highly recommended that a trial run be conducted prior to the wet season for the following reasons:

- ensure that all equipment is operational
- fine tune and improve the data collection exercise
- identify possible problems and seek solutions
- reinforce the tasks to be carried out by each crew member
- provide hands on training for any new crew member.

### C9.2 Equipment

Equipment specific to this method include:

- Helley-Smith bedload sampler with sample weighting system
- P 61 suspended sediment sampler with current meter
- ADCP in conjunction with a modified van Dorn sampler
- See Box C9.1 for further equipment requirements.

Two different sediment samplers are involved, one for the bedload sediment (Helley-Smith) and the other for the suspended sediment (P 61). The bedload weighing system is another piece of equipment required and is used in conjunction with the bedload sampler for determining the transport rate. This section details the operation of the Helley-Smith bedload sampler, P 61 suspended sediment sampler and the bedload weighing system. The latter is used in conjunction with the Helley-Smith to determine the bedload transport rate.

Sampler location on boats:

P 61 on the starboard side (right) and the bedload sampler on the port side (left).

<b>BOX C9.1 Equipment requirements for fluvial sediment sampling</b>	
Description	Quantity
<b>Bedload sampling</b>	
Bedload sampler	1
Sampling bags (minimum)	5
Bags for storage of samples	10*
Bedload weighing system	1
Bucket for submerged weighing (20 litres)	1
Wire to attached sampling bag to load cell	1
Stop watch	1
Battery 12V 5.7AH	2
Pencil	4
Screw driver for attaching sampling bags (if sampler not modified)	1
Standard (existing) winch	1
<b>Suspended sediment sampling</b>	
Suspended sediment sampler	1
Sampling bottles (minimum)	24
Plastic bottles for storage of samples	100*
Battery pack (if required)	1
Spare fuse for battery pack (if required)	3
Spare nozzle	2
Modified hanger bar	1
C2 connector	1
Modified powered winch	1
Thermometer	1
<b>Other Items</b>	
Data recording sheets (minimum)	12
12V truck batteries and battery charger	2
Generator	1
Trolley or wheelbarrow (if required)	1
Crane (if necessary)	1
Chain for securing crane to bridge	1
Safety vests	3
Safety cones	4
Flashing light	1
Tomahawk or wire cutters (for cutting four core cable)	1
Large container for storing samples	2

\* depending on the number of samples to be collected

### C9.3 Method

Sediment sampling involves not only the collection of samples but other related parameters as well. Samples/measurements to be taken are listed as follows:

- point velocity measurement at every location where suspended sediment sample is obtained
- suspended sediment sample
- bedload sample
- timing for each sediment sample (in seconds)
- submerged weight of each bedload sample
- water temperature.

All suspended sediment and bedload samples are to be sent to the Queensland Health Forensic Scientific Services (QHFSS) (or other approved laboratory) for analysis.

#### C9.3.1 When to measure

Sediments are mainly transported and deposited during flood events. The load is known to be higher during the rising limb than the recession, the rising limb being associated with the removal of stored sediments in the stream or the initial flush of mobile sediment from the land surface, particularly after a severe drought. Stream velocities, and thus sediment transport rates, are also usually higher for a given water level during the rising limb, than during the falling limb.

It is recommended that at least two sets of data be obtained at each sampling site for a flood event, one on the rising limb and the other on the recession limb. Ideally, the measurements should be taken during the period close to the maximum discharge. Figure C9.1 illustrates the two possible starting times, A and B.

Figure C9.1 Possible starting times (A and B) for sampling (for short duration floods)

In most cases, however, the selection of the starting times is very much dependent upon when the hydrographic team arrives and the time required to set up the equipment, particularly in a catchment of quick response. Figure C9.2 shows the period T, where the measurements can be taken.

Figure C9.2 Period (T) where samplings should be conducted

Measurements should cease when it takes a long time to collect the bedload (e.g. greater than about 10 minutes). For floods of longer duration (e.g. two or more days), advantage should be taken to collect more than two sets of data. In this case the selection of the starting times for sampling can be better decided. Figure C9.3 presents the possible starting times, A to D, for four sets of sediment sampling.

Figure C9.3 Possible starting times for sampling (for long duration floods)

### C9.3.2 Selecting verticals for sampling

The number of verticals required in a cross-section for sediment sampling is dependent upon the width, discharge distribution, accuracy sought, as well as the concentration variation across the river at the time of sampling. The location of each vertical is normally chosen based on:

- equally spaced verticals—with this method, the channel width at the water surface is divided into sections of equal width corresponding to the number of verticals required. This is a relatively easy method to use as the discharge need not be known prior
- strips of equal discharge—in this method, verticals are arranged according to the distribution of water discharge across the section. Each sampling vertical represents approximately equal portions of discharge. It is, however, a more involved process as the discharge must be computed prior to the sampling work
- consideration of the transverse distribution of sediment concentration—another method of selecting the verticals is to consider the transverse distribution of sediment concentration. In zones of large concentration variation, verticals are placed closer together whereas a lesser number of verticals is used on the floodplain.

**Recommendation: Location of verticals should be established before sampling for a possible range of flow depths to avoid additional workload in the field. Consult with the Project Manager.**

#### C9.3.2.1 Flow confined within main channel

Figure C9.4 shows an example of a selection of five equally spaced verticals (or six equal segments) across the stream. Where operationally possible, the distance between each vertical should not be more than 50 metres). This will, however, be stream/site-specific.

**Figure C9.4 Location of sampling points (flow confined within main channel)**

NOTE: for ADCP measurements, the distance from the bottom and top differs due to back scatter noise.

### C9.3.2.2 Over bank flow

In the event of significant over bank flows, more verticals should be placed in the main channel and less over the floodplain. Figure C9.5 presents an example where the main channel is divided into four equal portions and one vertical is placed in the middle of the floodplain.

Figure C9.5 Location of sampling points (significant over bank flow)

NOTE: for ADCP measurements, the distance from the bottom and top differs due to back scatter noise.

However, the selection of the verticals at some sites may differ from the above to meet specific program objectives and advice should be sought from the Project Manager. To minimise the time required for completing a set of sediment measurements (and also possible confusion), the sampling should be carried out as a separate exercise to the stream gauging. The latter requires a larger number of verticals.

### C9.3.3 Sampling methods for suspended sediments

There are two methods commonly used for sampling of suspended sediment, namely depth and point integration:

- **Depth integration**—in depth integration, the water–sediment mixture is taken continuously while the sampler is moving at a constant transit rate throughout a vertical. However, this method is limited to a depth of 4.5 m only for round trip sampling or 9 m for single trip. Furthermore, the transit rate of lowering or raising should be kept constant and should not exceed four-tenths of the mean velocity of a vertical. This condition must be adhered to for reliable results.
- **Point integration**—point integrated sampling involves an accumulation of water sediment mixture that is representative of the mean concentration at any selected point in a stream, over a short period of time. There is at least one selected point in a vertical.

Recommendation: In view of the operational difficulty and the depth constraint for the depth integration method, the more robust point integration method is recommended.

The number of sampling points in a vertical should vary according to the depth of the stream and the size of sediment in suspension. Commonly used methods are the one, two, three and five point methods. Their relative depths (measured from the water surface) are shown in Figures C9.4 and C9.5. More points selected would imply a longer duration of sampling (which may be counter productive) and result in higher costs for laboratory analyses. Hence the accuracy desired has to be balanced against cost and time.

Recommendation: Locations of the sampling points are recommended as follows:

*Flow confined within the main channel*

The middle vertical has five points at relative depths of 0.0, 0.2, 0.6, 0.8 and 1.0 The rest of the verticals are taken at relative depths of 0.2 and 0.8 (Figure C9.4).

*Over bank flow*

The five point sample is preferably taken in the deepest part of the main channel. For the rest of the verticals, samplings are taken at relative depths of 0.2 and 0.8 (Figure C9.5).

## C9.4 Equipment use

### C9.4.1 Acoustic Doppler current profiler

The acoustic Doppler current profiler (ADCP) is a standard instrument used in the collection of stream flow data. During this process, backscatter information from suspended sediment particles is also collected. This backscatter data can be used in the calculation of sediment loads (as water quality samples are collected in conjunction with each ADCP run). However, several points need to be considered before collecting point sediment samples with a P 61 sampler when using the ADCP:

- Blanking distance (blank after transmit)—the same transducer is used to receive the acoustic energy after transmitting a pulse. A short time (or a short sound travel distance) must pass before receiving is possible. This delay is called the blanking distance, and it allows the ADCP to ring down and become acoustically quiet before receiving the return signal. For the 600 kHz and 1200 kHz Rio Grande ADCPs, this distance is 25 cm.
- Near zone distance—there is also a shallow layer of water near the bottom for which the data is not used to compute discharge. When the ADCP sends out an acoustic pulse, a small amount of energy is transmitted in side lobes rather than in the direction of the ADCP beam. Side lobe reflection from the bottom can interfere with the water echoes. This gives erroneous velocities for the water near the bottom. WinRiver II does not use data in the region that may be affected. The ADCP has beams oriented at 20 degrees from the vertical, and the thickness of the side lobe layer is 6 per cent of the distance from the transducers to the bottom (see Figure C9.6).
- Edge estimates—as the name suggests, the flow for the edges is estimated using a power fit method of the data collected near the edge. In most cases for the collection of velocity data for load calculation this would not be an issue.

Figure C9.6 Side lobes

Source: Adapted from WinRiver diagram

Due to the methods outlined in Section C5.2, there can be issues due to the effects mentioned above; therefore, some considerations to these effects are required, i.e. modification to the location of the samples (shown in Figure C9.7) to allow for velocities to be extracted from the ADCP data. The operator should be able to quickly calculate the depths required from the output from WinRiver in the field, as the depth at which the ADCP is located (mounted on the boat) and the depth of the water are the influencing factors. The changes required are minimal and any major errors should occur due to the changes in the depth of sample; however, this would require verification before implementation. A detailed operational procedure on ADCP/Sediview applications is to be developed for approval as a standard method.

Figure C9.7 Unmeasured regions in the water column

### C9.4.2 Helley-Smith bedload sampler

Various types of bedload sampling equipment have been developed and used throughout the world. The Helley-Smith, a pressure difference type, is most commonly used overseas. This sampler is used for bedload sampling (see Figure C9.8). It has an intake nozzle which measures 76 mm by 76 mm. The unit weighs about 48 kg (105 lb), is constructed of a welded stainless steel assembly and has a stabiliser tail assembly. Bedload is caught in a polyester mono filament bag with a mesh opening of 0.2 mm which will not absorb water.

The sampler is best suited for sampling sediments in the range of 0.5 mm to 16 mm, which is appropriate for a large number of alluvial streams in Queensland. Larger sediments will need to be sampled with a larger sized nozzle (152 mm). The sampler is calibrated in a laboratory to determine its efficiency coefficient, defined as the ratio of the trapped sediment to that actually moved as bedload per unit of time. For the range of applications over medium to coarse sand and gravel bed (0.5 mm to 16 mm), the efficiency is close to 100 per cent for flow velocity of less than 3 m/second.

Figure C9.8 Helley-Smith bedload sampler (labelled A) and P 61 suspended sediment sampler (labelled B)

#### Sampler assembly

1. Remove the bedload sampler from the storage box.
2. Suspend the sampler in the water and adjust the suspension bracket so that the sampler (tail heavy) is at an angle of approximately 25 degrees from the horizontal. To achieve this, release the locking screws and move the sliding collar as an adjustment. Lock the screws and ensure that the suspension bracket is vertical.
3. To reduce the amount of time for set up on site, this step should have already been performed during the trial run prior to the actual measurement.
4. Place the sample bag, with seam uppermost, to the rear of the nozzle.
5. Place an elastic band on the sample bag in the location groove around the nozzle.
6. Slide the metal band over the elastic band, ensuring that the locating pins on the sides are in the secure position for a snug fit.

7. Secure the bag by pulling the clip into a locking position. The metal band and clip arrangement is a modification made to the original equipment for improving handling procedure in the field (original equipment has four clamps which can only be released by a screwdriver—a slow and frustrating job on a boat with a good chance of losing the screws holding the clamps).
8. Connect the hook to the eye at the rear of the sample bag.
9. Connect the C1 connector to the sliding collar.

### Sampling

1. Locate the sampling vertical position determined previously.
2. Lower the sampler carefully to the stream bed. When the tail makes contact, slowly lower the nozzle until it is sitting on the bed and start the stop watch; then record the sampler depth. **Care should be taken not to dig the nozzle into the stream bed.**
3. Collect the sample over a period long enough to give a decent sample (which will depend on the local velocity and bedload particle size). Raise the sampler immediately when the time expires.
4. Retrieve the sample bag. This task is easier to perform if the sampler is hauled into the boat.
5. Ensure that the sample bag is not filled by more than 40 per cent, else discard the sample and repeat the exercise with a reduced duration of sampling.
6. Weigh the wet sample, fully submerged in water and record its weight in grams (g).
7. **For samples that require laboratory particle size analysis (PSA), transfer the contents into another container. Ensure correct labelling and record the sample number.**
8. Discard the material from the sample and wash out the sample bag.
9. Record other details as required in the data recording sheet.
10. Assemble the sample bag and repeat sampling.
11. It is recommended that two or three readings be taken at each location. If uncertain or results differ markedly, an additional sample is justified.

### Dismantling the sampler

1. Remove the sample bag from the sampler for storage.
2. Ensure the lower clamp screws and clamps are secured to prevent loss or damage in the storage box. For recently modified samplers, ensure that the steel band is properly stored.
3. Return the sampler to the storage box for transportation.

For further procedures on sampling with the Helley-Smith bedload sampler refer to the Hydrological Services Operating instructions for bedload sampler model BLS-30 and model BLS-48

### C9.4.3 Bedload weighting system

This system is used to measure the submerged weight of the bedload sample. If the sediment sampling is carried out from a boat, it is highly desirable that the weighing be done on the boat itself, rather than saving the samples for weighing later while on land. When weighing is carried out immediately, the hydrographer is aware of the quality of the data and can make an informed decision as to whether another sample should be collected to improve reliability of the results.

#### Sampler operation

1. Remove the weighing system from the Peli-case container.
2. Assemble the weighing system (refer to schematic in Figure C9.9):
  - a. Connect the twisted pair wires between the back panel of the digital readout and the battery (e.g. 12V 5.7 AH Sonnenschein).
  - b. Plug the cable from the load cell into the rear panel of the digital readout.
  - c. Attach the two hooks to either end of the load cell.
  - d. Hang one end of the hook to a bar (or a rigid frame).
  - e. Switch on the digital readout and wait for about 10 seconds for unit to stabilise.
3. Ensure that the readout is set to register in g (not lbs), else press the 'weight selection' key.
4. Hang another empty sampling bag (for bedload) on the hook and totally immerse the bag into a weighing bucket part full of water (e.g. 20 L).
5. Zero the digital readout and remove the empty bag.
6. **You may need to provide a length of wire so that the sampling bag can be adjusted to allow for full immersion. Recently supplied bags are fitted with hanger lips for direct attachment to the load cell hook.**
7. Weigh the collected sample bag and its bedload fully immersed in the bucket of water. Place the bag gently onto the load cell, taking care not to snag the hook instantaneously. Record the weight in g.
8. If the boat is rocking or high wind conditions prevail, press the 'Autohold' (second blue button at the bottom of the readout) for 2 seconds. The 'Held' bar will flash on the indicator. The display will then search for a steady weight to lock onto. To turn off this mode, press the 'Autohold' for another 2 seconds.
9. An overflow occurs for weight in excess of 7000 g. This should not occur under normal operating conditions where the sediments consist of sand and gravel.

**WARNING: Do not overstress the load cell by the amount indicated in the manual (20 kg).**

10. Remove the sampling bag and sediments from the weighing assembly, discard the contents and thoroughly wash out the sampling bag.
11. The digital indicator weighing assembly does not need to be switched off if constantly in use, else repeat steps 4 and 5. Carry a spare battery for the weighing assembly.
12. Re-attach the emptied and washed sampling bag to the bedload sampler and repeat the exercise.

Figure C9.9 Schematic of bedload weighing system

In the past, all bedload samples were analysed in the laboratory for their dry weights. However, a weighing technique, based on the work by Carey (1984), is available whereby the submerged weight can be converted to the dry weight from the knowledge of the specific gravity of the bedload material. The relationship is given by:

$$W_d = [SG/(SG - 1)]W_s$$

where :

$W_d$  = dry weight

$SG$  = specific gravity

$W_s$  = submerged weight

For quartz material, the  $SG$  is equal to 2.65, and hence:

$$W_d = 1.606 W_s$$

A major advantage of this technique is that the weighing can be conducted in the field, thereby eliminating the time consuming exercise and costs involved in saving all the samples for laboratory analyses. Only samples that require particle sizing are kept and this represents only a very small quantity. This technique allows more samples to be collected and weighed at no additional costs, and hence improves the reliability of the data.

If the sediment sampling is carried out from a boat, it is highly desirable that the weighing be done on the boat itself, rather than saving the samples for weighing later on land. When weighing is carried out immediately, the hydrographer is aware of the quality of the data and can make an informed decision as to whether another sample should be collected to improve the reliability of the results.

This system was specifically designed for submerged weighing with the desired accuracy.

#### **C9.4.4 P 61 sampler and current meter**

The purpose of a suspended sediment sampler is to obtain a representative 'discrete' sample that is representative of the water-sediment mixture in a stream in the vicinity of the sampler. As such, the device is carefully constructed to satisfy several design criteria and it is also calibrated.

Integrating samplers collect a sample over a period of time to average out concentration fluctuations. The P 61 point integrating sampler for suspended sediment is the most common sampler employed in several countries and is used in this method (Figure C9.8). Developed by the US Geological Survey, the P 61 weighs about 48 kg, has a streamlined body and is cast in bronze with tail fins for orientation with the flow.

A solenoid activated valve opens and closes the nozzle during sampling. The water-sediment mixture enters the sampler into the container through the nozzle as air is exhausted through the air-exhaust opening. As such, the sampler should not be overfilled as the desired flow rates will not be attained and the sample will become contaminated by the flow circulating in through the nozzle and out through the exhaust opening.

#### **Sampler assembly**

1. Remove the P 61 from the transport container.
2. Connect the hanger bar to the P 61.
3. Assemble the current meter above the P 61 and lock it into position; then measure and record the distances between the current meter centreline and 1, the bottom of the P 61 (e.g. 0.42 m) and 2, and the P 61 intake nozzle centreline (e.g. 0.32 m).
4. Attach the C2 connector to the top end of the hanger bar.
5. There will be two cables dangling from the C2 connector. Plug one of the cables to the current meter. The other cable plugs into the head of the P 61. A locking lever ensures that the plug is secured.
6. On the winch end there will be four cables. Plug two cables to the readout unit of the current meter, while the remaining cables are connected to the battery pack.
7. Artificially rotate the current meter propeller and to confirm that a readout is registered, else interchange the cables. The cables should, however, be marked as 'Meter' or 'Battery' for easy identification.

8. Test the operation of the solenoid valve by holding the switch to the 'charge' position on the battery pack, until the meter registers a reading of about 48 V. Press the switch to the 'sample' position. A click on the P 61 indicates that the valve is operational.

**Possible problems at step 8**

The solenoid valve may be seized due to deposits formed from prolonged storage. Connect the power supply directly to the sampler, apply power, and strike the side of the sampler head with a rubber or wooden mallet. Never strike the nozzle.

Another reason for failure could be due to a blown fuse in the battery pack. Open the top of the battery cover and the fuse is located on the circuit board just beneath the cover (see Figure C9.10).

Check to see the fuse is operational. If not, change the fuse and replace the cover.

These additional 'repair type' jobs are not desirable during the flood event, thus reinforcing the point that the equipment should be well maintained and a trial run carried out prior to the wet season.

**Figure C9.10 Battery pack showing fuse location**

9. Open the head and insert the appropriate P 61 sampling bottle (cap removed) with the aluminium adaptor into the body of the P 61. Close the head slowly but firmly to ensure that it snaps into position. It's most convenient to have 13 pre-numbered P 61 sampling bottles which are capped after sampling, and then decanted into laboratory sample bottles back on the bank after each gauging.
10. The sampler is now ready. Take note of the horizontal distance between the sampler and the centre line of the boat.

**Sampling (point integration)**

1. Locate the sampling vertical.
2. Lower the sampler to the streambed to determine the depth of flow.
3. Raise the current meter to the appropriate position for velocity measurement.
4. Record the point velocity to enable determination of sample duration.
5. Raise (or lower) the P 61 by an appropriate distance to the previous position occupied by the current meter.

6. Press the switch on the battery pack to the 'sample' position for the desired sampling duration.
7. Release the switch on the battery box and hoist the sampler into the boat.
8. Open the head gently, ensuring that the head is always inclined upwards by at least 30 degrees to prevent spillage of the sample.
9. Remove the sample bottle with care.

NOTE: The 500 mL bottle must not be greater than 2/3 full (or 333 ml). If overfilled, discard the sample and repeat the suspended sediment sample collection with a shorter time period. The recommended volume is between 200 and 300 mL. Both levels should be marked on all sampling bottles prior to the event.

NOTE: Sampling time is dependent on stream velocity, so experimentations may be necessary at the start, or devise a local relationship between sampling time and current meter revs (e.g. 3000/C31 Prop 1 Revs).

10. Label the analysis bottle with the water quality field analysis number. Decant the sample into the analysis bottle for the laboratory or, if necessary, another container (e.g. 1 L bottle). This container can be decanted later to the analysis bottle on return to shore. This step isn't necessary during sampling if 13 pre-numbered P 61 sampling bottles are used.
11. Replace the sample bottle in the P 61 and close the head.
12. Move to the next sampling position in the vertical and repeat sampling steps 2 to 12 until all points in a vertical are completed.
13. Move to the next vertical, ensuring that the bedload sampling for the vertical has also been completed.
14. Repeat the process from steps 2 to 14 until all verticals for the cross-section have been sampled.
15. Obtain the temperature of the water (2 m from the bank) if no normal suit of samples are being obtained during the sample run.
16. Back at the bank, decant any samples remaining in P 61 sampling bottles into labelled laboratory sample bottles.

### Special care for P 61 samplers

The following care should be taken with the P 61 sampler:

- Handle the nozzle with care; if bent or burred, this will contribute to sampling error.
- Never submerge a sampler without a sample bottle in the body.
- Try not to overfill the sample bottle; otherwise water can flow back through the air exhaust opening into the head.
- Disassemble the head and clean (and dry) all parts after use to prevent the solenoid valve from seizure during storage.

## **C9.5 Equipment maintenance**

Sediment sampling presents a more complex exercise compared to the normal velocity measurements as:

- heavier equipment is involved
- the existing winch and cable arrangement has to be modified to accommodate the 4-core cable
- more tasks need to be performed by the hydrographic team.

To ensure a successful program, all equipment needs to be operational and it is vital to maintain it in a good state of repair. A bench test of all equipment is a prerequisite, including assembling the equipment on a boat, crane or vehicle. Other checks are also required such as:

- operation of the bedload sampler
- operation of the suspended sediment sampler
- sampling bags and bottles are in good condition
- accuracy and operation of the bedload weighing system
- modified winches are operational
- connector and hanger bar are in working condition
- battery pack for the suspended sediment sampler is operational
- modifications made to the boat, crane, etc. are in working condition.

## **C9.6 Sample handling**

### **C9.6.1 Bedload samples**

One sample is to be kept for each data set (i.e. one for every field sheet). This sample, from the deepest part of the channel, is sent to the laboratory for sieve analysis. To assist in the identification of the samples, each sample bag is labelled with the field water quality analysis number using a permanent marker. Details of the sample are completed on the field sheet.

### **C9.6.2 Suspended sediment samples**

The top and bottom suspended sediment samples from the deepest point are analysed for particle size analysis and sediment concentration. The remaining three suspended samples from the deepest point and the other verticals are to be sent for sediment concentration type analysis. The quantity of suspended sediment samples requiring labelling is therefore greater than the bedload samples.

## **C9.7 Quality assurance**

Complete and accurate completion of field sheets is necessary.

Control all possibility of sample contamination. Refer to Part B of this manual.

## Appendix C10 Sampling procedures for suspended solids and nutrients—application of water sampling technique

NOTE: The procedure in this appendix includes the triple-rinsing of sample containment bottles with site water prior to taking the sample. This is NOT appropriate when taking samples using specially-prepared bottles such as acid-washed or solvent-washed bottles. Nor is it appropriate if the sample bottles are supplied with the sample preservative already in the bottle (rinsing would lose the preservative). If a bottle for sample containment is supplied pre-cleaned by the analysing laboratory, no useful purpose is served by rinsing it on site. Although it is best practice to use specially-cleaned bottles supplied by the analysing laboratory for sample containment, new bottles, not specifically prepared may be used for sampling nutrients and suspended solids, and in this circumstance, triple-rinsing is appropriate.

### C10.1 Background for sampling procedures

Sampling involves the collection of a water sample directly into a suitable sampling container (direct collection) or collection into a temporary sampling container (intermediate container) with subsequent transfer into recommended bottles for storage. Appropriate containers and preservation methods are necessary to avoid risks of contamination of the sample and/or losses of analytes of interest during storage and transit prior to analysis. Details of appropriate sample containers and preservation methods are given in Appendix C8.

When sub-sampling from an intermediate container or when multiple sub-samples are drawn from a single sample, it is important to ensure the sample is homogenous prior to sub-sampling. The use of a sample splitting device (such as a churn splitter or similar) is recommended to achieve this.

There are a number of ways that samples can be collected and the choice of method will be determined by the analyte/s of interest, sampling objectives, and site specific conditions. Equipment used for intermediate and direct sample collection can include the following:

1. an extendable rod and bottle holder that allows for the sample bottle to be manually filled from the stream at a distance away from a stream bank (see section 3.1.1)
2. United States Geological Survey type isometric depth sampling equipment and/or a rope and weighted discrete sampling vessel (e.g. van Dorn sampler) for sampling from bridges, boats or overpasses
3. an automated pumping sampler (see section 3.1.2 Automatic Samplers) allows samples to be pumped from a point in stream to an intermediate sample containers (some refrigerated) for collection. Samplers can be triggered remotely or at pre-specified times or river heights
4. rising stage samplers (RSS) allow samples to be collected from a range of water depths with sample bottles filled as the river level rises during a flow event. Samples can only be collected on the rise of a flow event and are retrieved after the river level has receded (see section 3.1.1).

The choice of sampling equipment is largely dependent on the purpose for which the data is collected. Refer to section 2.1 for guidance on when and where to sample when applying these methods.

When collecting samples using any of these methods it is necessary to prevent contamination of samples (see section 3.5.1.).

Guidance on methods of sample collection provided below is of a general nature. As there are many different types of isometric samplers and van-Dorn like vessels, automatic, and rising-stage samplers available, methods may need to be modified slightly. In such cases, manufacturer instructions should be used for guidance. For all methods, once samples are collected, samples should be preserved and stored in bottles and as appropriate for each analyte of interest (see Appendix C8) and as guided by program objectives.

## C10.2 Manual sampling procedures

Where it has been deemed appropriate and safe to collect a discrete unit of water, a sample may be collected manually using an extendable pole sampler or an isokinetic, discrete depth sampler if appropriate.

### C10.2.1 Sampling using extendable pole sampler

1. Remove the lid from the 1 L sample bottle and attach the bottle to the end of a sampling rod.
2. Extend the sampling rod into the main flow of the stream. Submerge the bottle to a depth of at least 0.3 m, keeping the mouth end pointing down.
3. Whilst submerged, rotate the sampling rod 180 degrees to bring the mouth of the bottle facing up, and allow the bottle to fill with water; and retrieve bottle.
- 4\* Replace the lid and shake the bottle ensuring the inside of the bottle and the lid come into contact with the liquid. Discard the rinse liquid downstream of where you are sampling. Be sure to keep hands away from the mouth of the bottle and the underside of the lid.
- 5\* Repeat steps 3 to 4 so that the sample bottle and its lid are rinsed **twice** with stream water then proceed to step 6.
- 6\* Repeat step 1 to 3 to fill the bottle. Replace the lid and tighten. If sample requires freezing, ensure you leave 10–20 per cent space free.

\*These additional steps (bottle rinsing) only appropriate if specifically cleaned bottles are not being used to collect samples.

### C10.2.2 Manual sampling using isokinetic and discrete depth samplers

For methods to operate sampling for specific isokinetic samplers and van-Dorn like vessels, see manufacturer's instructions.

1. Lower the sampling device into the main flow of the stream to a depth of at least 0.3 m.
2. Whilst submerged, trigger the opening/closing device as per manufacturer instructions and allow the bottle to fill with water.
3. Remove the device from the water and agitate to resuspend solid material.
4. Open device and pour into storage bottle in a smooth and constant movement keeping materials in suspension.
5. Replace the lid on storage bottle and shake the bottle ensuring the inside of the bottle and the lid come into contact with the liquid.
6. Discard the liquid downstream of where you are sampling.
7. Repeat steps 4 to 6 so that sample device and storage bottle and its lid are rinsed **twice** with stream water, discard remaining water downstream.
8. Lower the sampling device into the main flow of the stream. Submerge the device to a depth of at least 0.3 m.

9. Whilst submerged, trigger the opening/closing device as per manufacturer instructions and allow the bottle to fill with water.
10. Remove the device from the water and agitate to resuspend solid material.
11. Open device and pour into storage bottle in a smooth and constant movement keeping materials in suspension.
12. Fill storage bottle, replace the lid and tighten. If sample requires freezing, ensure you leave 10–20 per cent space free

Figure C10.1 Van Dorn sampler

### C10.3 Automatic sampling procedures

Automatic samplers should be loaded with sample containers that are prepared using the necessary methods to avoid risks of contamination of the sample and/or losses of analytes of interest during storage and transit prior to analysis. Details of appropriate sample containers and preparation and preservation techniques are given in Appendix C8.

For guidance on sample bottle installation and sampler operation please refer to manufacturer instructions.

#### C10.3.1 Processing samples from automatic pumping samplers

1. Place lids on auto-sampler (intermediate) bottles whilst in the carousel.
2. Remove auto-sampler bottles individually in a sequential order from the auto-sampler carousel (Figure C15).
3. For each auto-sampler (intermediate) bottle follow steps 4 to 7.
4. Shake sample vigorously to resuspend settled material.
5. Remove lid from auto-sampler bottle and rinse storage sample bottle by carefully decanting a small amount of sample into the storage bottle. Shake and ensure the inside of the storage bottle and its lid comes into contact with the liquid then discard rinse water.
6. Repeat this process so that the bottle and its lid are rinsed **twice** with sample water.
7. Replace the lid on auto-sampler bottle and again shake vigorously to resuspended settled sediment then quickly decant sample into sample bottle for storage.

Figure C10.2 Removing samples from the auto-sampler

### C10.3.2 Processing samples from rising stage samplers

For guidance on sample bottle installation and sampler operation please refer to manufacturer instructions. Note that the sample inflow assembly of rising stage samplers require rinsing prior to use.

Once river levels have receded enough to allow safe access to the rising stage sampler proceed with sample collection.

1. Remove the in-flow assembly of one bottle from the rising stage sampler, starting from the top and secure sample bottle with a clean, dry lid; if the sample bottle used is an intermediate container please follow steps 4 to 7 in C10.3.1.
2. Label the sample bottle clearly indicating what its position in the rising stage sampler. Start numbering from the bottom up as this is the order in which the bottles filled in (i.e. number in the reverse order to the order of removal).

### C10.2 Sampling procedures for filtered nutrients

For any of the sampling methods above, the following steps should be followed when collecting filtered nutrient samples.

1. Refer to instructions for sample collection above. Once sample has been collected:
2. From the sample bottle take up 10 mL in a 60 mL syringe then fully extend the plunger and shake liquid to rinse the syringe ensuring all the inside surface comes into contact with the sample. Expel the water from the syringe downstream from the area where you are working. Repeat to rinse the syringe **twice**.
3. Completely fill the syringe with sample water from sample bottle and attach a filter (and pre-filter if required) to the end of the syringe as shown below (Figure 7a,b).
4. Discard the first 2 mL of the sample water pushed through the filters as a filter rinse (where possible) and then continue pushing another 10 mL of the water sample into the sample bottle.
5. Replace the lid on storage bottle and shake to rinse bottle and its lid. Repeat so that the storage bottle and its lid are rinsed with filtered sample water **twice**.

(a)

(b)

(c)

**Figure C10.3 Attaching the pre-filter (a) and filter (b) to the syringe and filtering sample into bottle 'E' (c)**

6. Remove filter and fill the syringe completely to 60 mL with sample water from sampling bottle, re-attach filter and use this to fill appropriate storage bottle (Figure 7c). If this becomes difficult, change the filter and/or pre-filter making sure you rinse at least 2 mL of sample water through them before filtering the water into the storage bottle again to the required analysis volume. Make sure to leave at least 10–20 per cent free space for water expansion. Secure the lid and store sample according to appropriate preservation techniques for later analysis.

## PART D Sampling bio-indicators of water quality and environmental health

### 4.1 Macro-invertebrate sampling and assessment

This methodology is based on the Queensland AusRivAS (Australian River Assessment System).

#### 4.1.1 Introduction to AusRivAS

The structure of plant and animal communities of rivers can give us a far more accurate picture of the condition or health of our waterways than measuring water quality parameters alone. Of these biological communities, macroinvertebrates (i.e. animals without backbones and large enough to be seen with the naked eye, e.g. prawns, shrimps, crayfish, snails, mussels and insects such as dragonflies, damselflies and mayflies) are most widely used because they are abundant and diverse, and are sensitive to changes in water quality, flow regime and habitat conditions. Impacts on these animals are relatively long lasting and can be detected for some time after the impact occurs. Impacts on a waterway can be varied: chemical spills, riparian vegetation removal, sand and gravel extraction, or stock access. All of these things can upset the balance, e.g. a chemical spill might kill a large proportion of the macroinvertebrate community, which is a major component of the diet of some fish, and consequently the fish population affected.

The AusRivAS (Australian River Assessment Scheme) model protocol (Simpson et al. 1997) adapts the River Invertebrate Prediction and Classification Scheme (RIVPACS) methods applied by Wright et al. (1984), Moss et al. (1987), Marchant et al. (1994) and aspects of protocols developed by Chessman (1995). This approach to assessing river health was adopted by the National River Health Program (NRHP—comprising the Monitoring River Health Initiative (MRHI) and First National Assessment of River Health (FNARH)). It allows rapid sampling methods to be used for the development of predictive models for macroinvertebrate communities within each state/territory, using a 'reference' site database. Comparisons may then be made between predicted and observed taxonomic compositions of macroinvertebrate communities in different habitats at a site in order to indicate the presence and magnitude of an impact on the site's ecological health. This approach can assess biological responses to changes in water quality and/or habitat condition in rivers and can be integrated with the existing network of physico-chemical water quality monitoring sites.

The actual protocol used (e.g. sampling design, number of sites, subsampling, replication, frequency of sampling, etc.) should be based on the objectives of the monitoring or assessment program. The AusRivAS protocol outlined below is meant for broad scale monitoring (e.g. catchment or regional basis). For smaller scale and specific issues, other methods using control and replicate sites (such as BACIP and multivariate equivalents) may be more appropriate (see Underwood 1993; ANZECC 2000).

The development of a standardised tool such as AusRivAS for broad scale bioassessment is dependent on three factors:

- use of the same biota
- use of the same approach to sampling and sample processing
- use of the same analytical methods for model development and use.

The data can also be analysed in different ways and used for other purposes such as impact assessments, condition and trend reporting, biodiversity and biogeographic studies.

It should be noted that this protocol is for use only in freshwater reaches of rivers and not for use in estuaries or tidal reaches of lowland rivers. Although the general approach may be valid, substantial additional work must be performed prior to its adoption in estuarine and marine conditions.

### 4.1.2 Sampling program

#### Important note:

The sampling program described below was followed by the former Department of Natural Resources and Water (NRW) (now incorporated into the Department of Environment and Resource Management—DERM) in developing the AusRivAS predictive models for Queensland rivers. Anyone intending to utilise the models for assessing riverine sites must follow this procedure. Data can then be input into the models run by DERM. Those not intending to use the DERM models but still interested in developing and implementing a broad scale biological monitoring and assessment program for their streams and rivers can also follow this procedure. The advantage of doing so is that a standard method is followed which would permit direct temporal and spatial comparisons of data, and allow sites to be compared with existing MRHI and FNARH reference and test sites.

### 4.1.3 Site selection

Reference and test sites in Queensland were initially selected for the MRHI program using protocols outlined in the River Bioassessment Manual (Davies 1994). Reference sites were those 'least disturbed' sites sampled for the production of a database used in the construction of predictive bioassessment models (e.g. RIVPACS of Wright et al. 1984). Test sites were those identified to be of importance in assessing the condition of a river known or perceived to be experiencing an impact from water quality or habitat degradation. These protocols were adapted by QNR&W into a list of criteria to which each site was subjected. Table 4.1 lists the 10 selection criteria currently used to determine whether sites are in reference condition.

The input of additional information from outside sources may potentially result in modifications to these assessments. This method will provide a better characterisation of the sites based on numerical categorisation bringing the assessments into line with other programs undertaken by QNR&W. Each criterion relates to an aspect of human activity that impacts on freshwater ecosystems, where impact is defined as a 'change from natural condition'. Each criterion is given a score according to the following categories:

1. very major impact
2. major impact
3. moderate impact
4. minor impact
5. indiscernible impact.

**Table 4.1 Selection criteria used to determine eligibility for reference site status**

No.	Reference condition selection criteria
1	Influence of intensive agriculture upstream.* Intensive agriculture is that which involves irrigation, widespread soil disturbance, use of agrochemicals and pine plantations. Dry-land grazing does not fall into this category.
2	Influence of major extractive industry (current or historical) upstream.* This includes mines, quarries and sand/gravel extraction.
3	Influence of major urban area upstream. This will be relative to population size, river size and distance between the site and the impact.
4	Influence of significant point-source waste water discharge upstream.* Exceptions can be made for small discharges into large rivers.
5	Influence of dam or major weir.* Sites within the ponded area of impoundments also fail. Sites failing this criterion automatically fail the overall assessment.
6	Influence of alteration to seasonal flow regime. This may be due to abstraction or regulation further upstream than the coverage by criterion 5. Includes either an increase or decrease in seasonal flow.
7	Influence of alteration to riparian zone. Riparian vegetation should be intact and dominated by native species.
8	Influence of erosion and damage by stock on riparian zone and banks. Stock damage to the stream bed may be included in this category.
9	Influence of major geomorphological change on stream channel. Geomorphological change includes bank slumping, shallowing, braiding and unnatural aggradation or degradation.
10	Influence of alteration to instream conditions and habitats. This may be due to excessive algal and macrophyte growth, by sedimentation and siltation, by reduction in habitat diversity by drowning or drying out of habitats (e.g. riffles) or by direct access.

\* Note: the level of impact at a site will generally decrease with the distance from the source of impact

Sites are assessed using the total score for the 10 criteria. Currently, those sites that have a total greater than 44 are deemed to be reference sites. Sites that are given a score of 1, 2 or 3 for criterion 5 (no dam or major weir upstream) cannot be reference sites.

#### 4.1.4 Sampling frequency

Any program that attempts to standardise sampling protocols across Australia must take into account the occurrence of rivers encompassing a wide range of predictability and seasonality in river hydrology, life histories of biota and river habitat types. Whether a strong seasonality occurs or not, a minimum number of samples must be taken over time to allow collection of adequate macroinvertebrate taxa information for reference site classification.

The overall aim of the sampling protocol is to ensure that the broadest range of biota are captured at a site by sampling a number of habitats and on a number of occasions. To ensure standardisation and compatibility of data sets, the following protocol was followed for all sites, whether reference or test sites.

The sampling protocol for Queensland rivers and streams requires a minimum of two sample sets in one year. These are sampled on a 'seasonal' basis from October to December (early wet—when flow has been established for at least four weeks) and May to July (late wet—recessional baseflows when flow had declined to a sampleable level, without significant flood peaks). The early wet samples are identified as 'spring' samples; the late wet as 'autumn' samples.

For the model development, each site was sampled twice in one year and the data from the two sample sets were used separately to develop seasonal models, and combined to develop an annual model.

#### 4.1.5 Habitats sampled

Each reach of a stream may have several habitats. If a habitat accounts for more than 10 per cent of the stream reach then it should be considered for sampling. The predominant habitat types are identified at each site and appropriate ones sampled separately. In Queensland, only two habitats are sampled, an edge sample and a bed sample. The first choice of bed habitat is a riffle; failing this a rocky bed is sampled and, finally, a sandy bed. Ensure that the type of bed sampled is recorded on the field sheet.

Separate sampling of distinct habitat types is prescribed because each habitat has a potentially distinct fauna. The performance of the predictive models will therefore not be confounded by differences in habitat availability between sites and times. AusRivAS models have been developed for edge and pool habitats in Queensland for autumn and spring seasons, as well as a combined season annual model. Riffle models may be developed in the future.

In Queensland, the habitats most likely to be encountered are as follows.

##### 4.1.5.1 Riffle

This is a reach of relatively steep, shallow (less than 0.3 m), fast flowing (more than 0.2 m/s) and broken water over stony beds (see Figure 4.1).

Figure 4.1 Riffle habitats

##### 4.1.5.2 Run

A run is a reach of relatively deep and fast flowing, unbroken water over a sandy, stony or rocky bed (see Figure 4.2). These are features of streams during a flood event, below dams where riffles have been 'drowned' or in steep gradient streams flowing through gorges. Under normal flow conditions, it is best to avoid sampling this type of reach. However, pools and riffles may become runs during flood events (e.g. in April) and it may be necessary to sample the area. If possible, delay sampling until flow recedes.

**Figure 4.2 Run habitat**

#### **4.1.5.3 Pool bed**

Pool bed habitats are zones of relatively deep, stationary or very slow flowing water over silty, sandy, stony or rocky beds. This habitat occurs in the main channel and should not be confused with backwaters, which occur as indentations of the bank. Waterholes are generally pools with silty/sandy beds while pools with rocky/gravel beds are often found in steep areas. The velocity will indicate whether it is a pool or run. The classification factor is the bed type, i.e. sandy/silty beds and rocky/gravel beds (see Figure 4.3).

**Figure 4.3 Sandy bed and rocky bed habitats**

#### **4.1.5.4 Edge/backwater**

Edges (or banks and underbank areas) are along the bank where there is little or no current and extend to approximately 0.5 m from the bank. There may be some terrestrial vegetation (e.g. paragrass, sedges) or tree roots, or the area may be bare (e.g. waterholes in drier areas). A backwater is a zone where the bank indents and a pool of water forms away from the main channel (e.g. ox-bow, off-cut channel). The backwater may have a circular or back flow, and a silty bed with accumulated plant litter (leaves, twigs. etc.) (See Figure 4.4).

**Figure 4.4 Edge habitats**

#### **4.1.5.5 Macrophytes**

Macrophyte habitats are areas where emergent, submergent and floating macrophytes or aquatic plants are present and can occur in slow to fast flowing areas. Macrophytes that you are likely to encounter include milfoil (*Myriophyllum* spp.), hornwort (*Ceratophyllum demersum*), waterfern (*Azolla* spp.), salvinia (*Salvinia molesta*), duckweed, water thyme (*Hydrilla verticillata*), water primrose (*Ludwigia* spp.), water hyacinth (*Eichhornia crassipes*), waterlilies (*Nymphaea* spp.), pondweeds (*Potamogeton* spp.) and ribbonweed (*Vallisneria* spp.). These areas are designated on the field data sheet as 'macrophytes' (see Figure 4.5). Although reference and some test site sampling has been done, it is not envisaged that a model will be developed for this habitat. Therefore, this habitat is no longer sampled as part of the AusRivAS approach, although it may still be sampled for other purposes, e.g. nutrient enrichment studies and flow assessments.

**Figure 4.5 Macrophyte habitats**

#### **4.1.6 Preparing for a field trip**

Before embarking on a field trip, some preparation is needed. Appendix H1 and Figures 4.6 and D4.7 outline a list of the equipment needed for macroinvertebrate sampling.

Figure 4.6 Monitoring and sampling gear

Figure 4.7 Monitoring and bug picking gear

#### 4.1.7 Field sheets

Prior to water or macroinvertebrate sampling, information must be recorded on field sheets about the site. This includes information about the whole reach (100 m section of the river), the habitats sampled, and the surrounding terrestrial environment. There are four types of field sheets used by DERM to record information about a site:

- Queensland Site Information Sheet (Appendix H2)
- Water Quality Sampling Field Sheet (Appendix H3)
- Habitat Assessment Field Sheet (Appendix H5)
- Task Sheet (Appendix H6).

Note: All DERM field sheets contain common essential information:

- **Site number:** All sites are allocated a site number, based on the catchment and subcatchment and whether it is a hydrographic gauging station or a 'miscellaneous' site. These numbers contain seven alphanumeric characters: the first three numbers indicate which catchment the sites are in (e.g. 136); the fourth digit, the subcatchment; and the final three, the site. For example, a site with the site code 136017B shows that this site is in the Burnett River catchment (136), within the 0 subcatchment, and the site number within this subcatchment is 17B. Sites with a letter as the final character indicates that these sites have or have had a flow gauging station nearby

- **Site name:** describes where the site is on the river, e.g. Burnett River at Gayndah Flume.

#### 4.1.8 Water quality sampling

All water quality measurements and water samples are required to be collected upstream of the biological sampling area and of the water sample collector. They should be taken from a representative section of the stream, slightly flowing if possible, at a depth of 10–20 cm. Care must be taken to avoid sampling too close to the edge and too close to aquatic plants. Field alkalinity measurements are taken using a titration kit (Figure 4.6). Appropriately calibrated meters are needed to measure temperature, conductivity, dissolved oxygen, pH and turbidity (Figure 4.7). The results are recorded on the Water Quality Sampling Field Sheet (Appendix H3).

The water quality samples are collected in prepared bottles, details completed on the sample bottles, samples preserved correctly, external paperwork completed and samples cross-referenced on the Water Quality Sampling Field Sheet. DERM routinely collects two water samples: one for major ions analysis and one for nutrient analysis (nitrogen and phosphorus). Refer to Part B of this manual for appropriate sampling methodology.

#### 4.1.9 Biological sampling

##### 4.1.9.1 General considerations

Sampling should not be conducted when streams are in flood unless the impact of flood is being investigated. If, during the scheduled sampling period, sites are consistently in flood, sampling should resume 4–6 weeks after floods have subsided. The study site is a 100 m length of stream (50 m upstream and 50 m downstream of the point of entry).

All macroinvertebrate samples should be collected with a standard 250 µm mesh dip net. Recommended dimensions are a triangular 250 mm x 250 mm x 250 mm opening and 50–75 cm depth, and with a 1–1.5 m aluminium handle. The net should be checked for damage prior to a sampling trip and washed thoroughly after sampling each habitat to remove animals left from previous sampling. Sample a total distance of 10 m, covering a variety of velocities, if possible, and different examples of the habitat. (Nets are available from the Australian Centre for Tropical Freshwater Research, James Cook University.)

##### 4.1.9.2 Sampling the habitats

###### Sampling the riffle

While holding the net downstream with its mouth facing the sampling area, disturb the substratum by digging the foot well into the stones and turning them over. Turn and rub stones by hand to dislodge organisms. Continue this process working upstream over a total distance of 10 m, covering both the fastest and slowest flowing sections of the riffle. Do not include material from macrophytes and/or wood debris located in the riffle. It may be necessary to collect the sample from more than one riffle if the first riffle is less than 10 m in length.

###### Sampling the pool/bed:

Disturb the substratum by kicking with your feet. If the stream is flowing, hold the net downstream with the mouth facing the disturbed area. If there is no discharge you will have to use a short sweeping action with the net while stirring up the bed. The suspended benthic animals are captured as the net sweeps through the cloud of suspended matter.

Note: Silty/sandy beds—preferably select an area with plant litter (not macrophytes) rather than an area of clean sand.

Note: Rocky/gravel beds—if the rocks are too large to kick over without damaging your foot, wash about 10 rocks of a range of sizes, scrubbing gently with the hands or a light brush into the net. Leave the rocks out of the water to allow cryptic specimens to emerge. These can then be hand picked. Be careful, as leaving the rocks in the sun for too long will dry out and kill the animals. Again, avoid areas where macrophytes are present.

### **Sampling the edge**

Locate an edge area with little or no current or aquatic vegetation (stands of paragrass are acceptable as edge habitat). An alcove or backwater with abundant benthic leaf litter is preferable. Suitable areas include fine organic/silt deposits and/or trailing vegetation and are often indicated by the presence of surface-dwelling insects. In waterholes you may have no choice but to sample the bare edges, perhaps with some tree roots. Using short upward sweeping movements at right angles to the bank, sample a total bank length of 10 m. Stir up the bottom while doing so, ensuring that benthic animals are suspended and then caught when sweeping through the cloud of suspended material. There may be aquatic plants (macrophytes) along the banks and in backwaters. Avoid sampling these areas.

### **Sampling the macrophytes:**

Locate an area with dense aquatic vegetation (if present). Vigorously sweep the net within the aquatic vegetation over a length of 10 m. Aim to sample the upper, middle and lower portions of the plants. A combination of short lateral sweeps with vertical lifts will aid in dislodging and catching suspended organisms. (This habitat was not modelled for AusRivAS.)

#### **4.1.9.3 Picking the sample**

Nationally, two methods are used for collecting organisms: field picking and laboratory picking. The choice of which method to adopt will be influenced by considerations of the objective of the study, precision required, time, cost and balance of effort in the field versus laboratory. Either method may be used, although it is preferable to maintain the same technique for all sites. For Queensland, the field picking option has been adopted as the preferred standard method.

Field picking is considered to be more subjective. However, with sufficient training, care and objectivity, it does provide a cost-effective alternative to laboratory picking.

#### **Field picking:**

Treat samples from each habitat separately unless it is part of the project design to have composite samples. It is recommended that the sample is initially separated into two fractions (the small organic and substrate material and large rocks and leaf litter) using a 1 cm panning sieve (cheap aluminium ones are available from local camping stores). Sort through these fractions, a small amount at a time, retaining the residue for QA/QC requirements (see below). Work progressively through the sample, replacing picked material with remaining parts of the sample as picking progresses.

Half fill a vial with 70 per cent alcohol (methylated spirits). Ensure the container you use is large enough. If the animals you collect take up more than 30 per cent of the volume, use a larger container. Use alcohol stable vials to avoid vial cracking and sample loss.

Pick for a minimum of 30 minutes, using tweezers and pipettes, and record the total abundance using a hand held counter.

Collect only 10 of any one type (family and, in some cases, order) of animal. If you are not sure of the identity, then collect all of the uncertain ones. At least 30 midge larvae (Chironomidae) should be collected to ensure adequate representation of the sub-families.

At the start of your field pick, the common and abundant taxa should be picked for about the first five minutes. After that, the major picking effort should be directed at finding the less common, inconspicuous taxa. After 10 minutes no more common taxa should be picked unless it is suspected that a particular common form contains more than one family, or it was a common taxon overlooked initially.

If you get 200 animals (about 10 of each type plus at least 30 Chironomidae) then stop at the end of this 30 minute period. If, at the end of the 30 minutes, you have not collected 200 animals then you should collect for a further 10 minutes. If any new taxa are found in those 10 minutes, extend the picking time by another 10 minutes. Follow this procedure until either no new taxa are found, 200 animals have been collected or 60 minutes have been spent on picking. Note the picking time on the field sheet.

Particular care should be taken to search for the groups that can be commonly missed when live sorting (cryptic taxa):

- |                                 |  |
|---------------------------------|--|
| Corbiculidae (juveniles)        | Oligochaeta (including broken fragments) |
| Chironomidae (larvae and pupae) | Elmidae (larvae)                         |
| Empididae (larvae)              | Hydrophilidae (larvae and adults)        |
| Hydroptilidae (larvae)          | Simuliidae (larvae)                      |
| Ceratopogonidae (larvae)        |  |

If it is a really poor sample (i.e. urban tributary or sandy stream) with very few animals in total, then stop at 60 minutes. Make it clear on the field sheet that it was a poor quality site or sample and why that is so. A poor sample may also result from a bad collection, e.g. a sample taken during high flows over areas which were dry a few days before.

If it is raining or cold, or conditions of poor light exist due to cloud cover or approaching twilight, the sample must be taken back to the vehicle, motel, camp, etc. for sorting undercover and with improved light conditions.

Ensure a completed label is placed in the vial noting the project name, site number and name, sampling date, habitat sampled, sample collector and picker and any relevant notes (see Figure 4.8).

Remove some of the diluted alcohol in the vial using a mesh-covered syringe and replace with fresh 70 per cent alcohol. Fill to top and ensure the lid is tightly screwed on.

<b>RIVER BIOASSESSMENT PROGRAM</b>

Site No: [           ]	Habitat: _____
Collector: _____	Picker: _____
Collecting Method: _____	
Picking Method: _____	

Figure 4.8 Label for picked sample

**Laboratory picking:**

The entire sample is preserved in the field using 70 per cent methylated spirits, a completed label included and the sample adequately stored for transport to the laboratory. Large plastic screw-top jars or heavy-duty plastic bags stored in a polydrum are suitable containers.

#### 4.1.9.4 Field picking quality assurance/quality control (QA/QC)

The residues of 10 per cent of all samples taken in the field are retained for analysis. The entire residue is preserved in the field using 70 per cent methylated spirits, a completed label included and the sample adequately stored for transport to the laboratory. Half of these samples are put aside for external analysis; the other half are subsampled and 10 per cent of each sample are analysed by the unit's staff. The data is analysed, compared to the sample picked in the field, and reports written.

#### 4.1.9.5 Handy tips for field picking

Use waterproof paper for field sheets.

Only use pencil to fill in field sheets and sample labels; ink and felt tip pens smudge and run.

Some macroinvertebrate groups are fairly cryptic, i.e. difficult to detect, particularly in the first 15–30 minutes after collection. To counteract this phenomenon and ensure that you pick a representative sample from the habitat, it is suggested that all the habitats be sampled before picking begins.

Remember to label each sample as you put it into the tray or bucket. The first sample will then have had sufficient time to rest and the animals will have become more active and easier to see (although not necessarily easier to pick). With labels:

- place them inside the vial
- preferably, DO NOT use gummed (stick on) labels
- if you have to use gummed labels, DO NOT remove the backing paper (the animals stick to the label and are irretrievable).

Buckets are always useful—to carry rinsing water, to put your rock collection in, and to split your sample if it is too big. Ensure that you take at least two per person, preferably more. A couple of buckets with lids are also useful if samples need to be transported before picking.

For safety reasons, at least two people should conduct the field sampling. Field time can be best utilised with one person conducting the macroinvertebrate and water quality sampling and the other filling out the field sheets. Once the samples are collected, these can be live picked in the field by both persons to save time.

#### 4.1.10 Laboratory macroinvertebrate sample processing

It is recommended that a registration system be set up for all samples collected. A standard form is recommended for this purpose. These sheets should be filled out for all samples within 24 hours of return from field trips. Cross-checking should be performed so that samples recorded on field sheets are present, labels are accurate and legible and bottles filled with preservative. Labels should have the site name, location code, habitat, sampling method, collector's name, picker's name and date on them (Figure 4.8).

All registration sheets should be filed appropriately and samples stored in labelled lidded containers (to minimise evaporation) in an approved fire-proof storage area. Each box should contain a logical group of samples to facilitate sample identification and handling.

Software for sample registration and archiving should enable integration with the sample database (see below).

#### 4.1.10.1 Sample identification and enumeration

##### 4.1.10.1.1 Field-picked samples

Ensure adequate ventilation in the workplace. Rinse the sample with gently running water through a 250 µm sieve. Flush the sieve contents into a large petri dish with water from a squeeze bottle. Always use water when working with the sample. When finished, replace the water with preservative.

Place the petri dish under a stereomicroscope which is correctly adjusted for your vision and work posture (refer to manufacturer's instructions). Use a vial of suitable size to take the collection of specimens in the petri dish with label inserted. The label should have the following information: collection number, location code, site name, collection date, habitat, sample identifier and the identification date (Figure 4.8). Use pencil or alcohol-proof ink to fill in details. Half fill the vial with 70 per cent ethanol.

A dedicated tally sheet (Appendix H7) should be developed for recording the identities and numbers of all taxa in a sample. The sheet should allow listing of the taxonomic key used for identification for each family, the person making the identification, the site, date and sample code.

Organisms are identified to family level with the exception of lower Phyla (Porifera, Nematoda, Nemertea, etc.) Oligochaetes (freshwater worms), Acarina (mites), and microcrustacea (Ostracoda, Copepoda, Cladocera) for which family level identification is optional (it may improve resolution but is time consuming). Chironomids should be identified to sub-family level. Appendix H8 lists the keys used by DERM.

Select specimens and follow the appropriate taxonomic keys to family level. If uncertain about the identity obtain a second opinion from a colleague/local specialist. If a new family is suspected or other significant issues arise in taxonomic identification, contact the relevant national taxonomic specialist.

Identify each specimen, place in the vial and mark the tally sheet. When all specimens have been counted, record the total tally for each taxon. Place the vial, filled with preservative, in an evaporation-proof container (e.g. a large screw-top glass jar) in a suitable storage location.

Transfer the collected data to an electronic spreadsheet or database. At the completion of the sample series, the database should be cross-checked against the data sheets to ensure that there are no transcription errors.

All sorted collections should be archived, preferably lodged with a regional or state/territory museum, so that any future taxonomic revisions or more detailed identifications can be conducted if required. The relevant museum staff should be consulted well in advance of submission of specimens.

##### 4.1.10.1.2 Fully preserved samples

Tip the preserved sample into a series of 10 mm and 250 mm sieves and thoroughly wash the sample. If there are large coarse fractions (sticks, leaves, etc.) wash these over the sieves and place them into a sorting tray. Examine these coarse fractions preferably using a magnifying glass, for approximately 10 minutes, ensuring that any macroinvertebrates attached to the coarse fractions are collected. Note: keep an eye out for stick and leaf-cased Trichoptera.

Evenly distribute the remaining smaller fractions from the sieves into a subsampler. The subsampler used and recommended by DERM is a modified Marchant subsampler (Marchant, 1989) (see Figure 4.9). This subsampler contains 100 circular cells, each 3.5 cm in diameter x 3.5 cm deep. Fill the subsampler until the water level reaches the top of the cells, secure the lid, and rotate vigorously in both directions until the sample is distributed throughout the cells. Using

a vacuum pump, subsample 10 per cent (10 cells) of the whole sample, ensuring every 1 per cent (1 cell) of the subsample is stored in separate containers.

Sort and identify the subsamples in the procedure described above (see live picking), noting how many new taxa there are in every 1 per cent subsample sorted. If this procedure is used for internal QA/QC checks on field picking, only 10–15 organisms of each family are identified and recorded. However, if the subsampling is required for quantitative sampling, sort and identify all taxa from the subsamples.

**Figure 4.9 Modified Marchant subsampler**

The long-term aim in the development of this protocol is to further identify samples to genus and/or species level, in order to improve the predictive power of the resultant models. Thus a high emphasis should be placed on the development of a systematic and well designed data entry and sample archiving system. For certain objectives such as impact assessments, it is advisable to identify the animals to the lowest possible taxonomic level, preferably species, although, at present, AusRivAS models are available only for family level assessment. Identifications made at species/genus level can be converted into family level data and run through the models, but the converse is not possible without re-identification.

#### **4.1.10.2 Laboratory identifications QA/QC**

Internal QA/QC checks on laboratory identifications are performed on staff, by staff, on a regular basis. At each round of QA/QC, a person is assigned to analyse a sample identified by another. Samples identified during the previous fortnight are selected at random and re-identified. The resultant taxa lists are compared and discrepancies in identification checked by other staff in the unit. Any errors are discussed with the original identifier (both misidentifications and errors of enumeration) and a report prepared which is read and signed by all members that underwent the QA/QC check. Under NRHP guidelines, error rates greater than 10 per cent in identification and counting are not acceptable.

#### **4.1.11 Database entry and software support**

A dedicated database should be established to allow for entry, storage, checking and distribution of data and for manipulation of data for subsequent analysis. No specific software package is recommended, although consideration should be given to the ultimate size of the database, the need for ongoing addition of data as the protocol develops into a usable tool, and

compatibility with existing systems and software. The database must allow data files to be translated into ASCII format. Data can be entered by a standard spreadsheet (e.g. Excel) and exported to the database (e.g. ACCESS).

Anyone wishing to utilise the AusRivAS model must comply with data formatting indicated in the AusRivAS Manual (visit <[www.ausrivas.canberra.edu.au](http://www.ausrivas.canberra.edu.au)> or Simpson et al. 1997). The appropriate predictor variables should also be considered. Appendix H9 lists the predictor variables used for the Queensland models.

#### 4.1.11.1 Biological data

An appropriate data entry spreadsheet has been designed as recommended by Simpson et al. (1997). Enter all sample data into a unique file and all sets must match exactly. When data is entered it must be cross-checked against data entry sheets. Use the national taxonomic codes for all families (Appendix H10). Use of this coding will allow compatibility between data sets at the agency, state/territory and national levels and will greatly expedite comparisons and future taxonomic efforts.

#### 4.1.11.2 Habitat data

Design a data entry spreadsheet. Perform all calculations to the raw data to conform with the data requirements for later analysis. Enter this processed data for a site into a unique file. Cross-check the data against field sheets. Use the same site code and the relevant date and sample coding to allow integration of habitat data with the biological samples for later statistical analysis.

## 4.2 Blue-green algae (cyanobacteria) sampling and assessment

### 4.2.1 Introduction to blue-green algae

Planktonic cyanobacteria, or blue-green algae, are a common, naturally occurring and integral component of many aquatic ecosystems. As such they often cause no obvious ecological problems. However, a small group of genera produce toxins (cyanotoxins) that have caused sporadic cases of animal poisoning, have been implicated in human hepatoenteritis, and have led to human fatalities.

Cyanobacteria pose a potential health risk through the consumption of water supplies contaminated by cyanotoxins, and through direct exposure to cyanotoxins during water-based recreational activities (i.e. skiing, bathing, wading, boating, etc.). Cyanotoxins have been isolated, identified, and characterised from a number of cyanobacterial taxa, and the ones reported from Australian freshwater to date are presented in Table 4.2.

To reduce the risks of adverse health impacts caused by cyanobacteria, it is essential to routinely monitor water supplies for their presence on a quantitative basis and, where necessary, test for the presence and concentration of their toxins.

**Table 4.2 Potentially toxic cyanobacteria reported from Australian freshwaters**

Toxic species	Cyanotoxin	Target organ
<i>Anabaena circinalis</i>	saxitoxins	nervous system
<i>Aphanizomenon ovalisporum</i>	cylindrospermopsin	liver
<i>Cylindrospermopsis raciborskii</i>	cylindrospermopsin	liver
<i>Microcystis aeruginosa</i>	microcystins	liver
<i>Nodularia spumigena</i>	nodularins	liver
<i>Nostoc cf. linkea</i>	unidentified	liver

## 4.2.2 Guidelines for assessing blue-green algae

The Australian Drinking Water Guidelines (NH&MRC/ARMCANZ 1996) currently provide guidance for one of the four major classes of cyanotoxins found in Australian freshwaters. The guidelines recommend that the concentration of total microcystins in drinking water not exceed  $1.3 \mu\text{g L}^{-1}$  (expressed as microcystin-LR toxicity equivalents). Due to the lack of adequate data, no guideline values have been set for the other three classes of cyanotoxins. Given the presence of cyanotoxins other than microcystins in Queensland freshwaters, DERM recommends a conservative approach be adopted wherein a value of  $1.0 \mu\text{g L}^{-1}$  is used for cylindrospermopsin and Paralytic Shellfish Poisons (PSPs) as an interim guidance level until sufficient data has been collected to allow for the development of individual guidelines for these two cyanotoxins.

The risk of adverse health effects through recreational contact in water containing cyanobacteria varies with the concentration of cyanobacteria and the nature of the activity. The risk is derived from contact with both the known cyanotoxins produced by the species listed in the World Health Organization (WHO) Guidelines (Table 4.3), as well as from a group of yet unidentified, non-specific compounds produced by cyanobacterial taxa which have been recorded as producing symptoms ranging from mild skin irritations to nausea, and pneumonia-like symptoms.

**Table 4.3 WHO guidelines for safe practice in managing bathing waters which may produce or contain cyanobacterial cells (after Chorus & Bartram 1999)**

Hazard status	Guidance level or situation	Health risks	Recommended action
High	Cyanobacterial scum formation in contact recreation areas or > 100 000 cells total cyanobacteria $\text{mL}^{-1}$ or > $50 \mu\text{g L}^{-1}$ chlorophyll-a with dominance of cyanobacteria or > $12.5 \text{ mm}^3 \text{ L}^{-1}$ cyanobacterial biomass	Short-term adverse health outcomes such as skin irritations or gastrointestinal illness following contact or accidental ingestion  Severe acute poisoning is possible in worst ingestion cases	Immediate action to prevent contact with scums  Signs to indicate HIGH alert level—warning of danger for swimming and other water contact activities
Moderate	20 000–100 000 cells total cyanobacteria $\text{mL}^{-1}$ or $10\text{--}50 \mu\text{g L}^{-1}$ chlorophyll-a with dominance of cyanobacteria or $2.5\text{--}12.5 \text{ mm}^3 \text{ L}^{-1}$ cyanobacterial biomass	Short-term adverse health outcomes, e.g. skin irritations, gastrointestinal illness, probably at low frequency	Signs to indicate MODERATE alert level—increased health risk for swimming and other water contact activities
Low	< 20 000 cells total cyanobacteria $\text{mL}^{-1}$ or < $10 \mu\text{g L}^{-1}$ chlorophyll-a with dominance of cyanobacteria or < $2.5 \text{ mm}^3 \text{ L}^{-1}$ cyanobacterial biomass	Short-term adverse health outcomes unlikely	Cyanobacteria either absent or present at low levels—continue monitoring

The provisional guidelines for cyanobacteria in bathing water as adopted by DERM are presented in Table 4.4. These guidelines are based on the WHO guidelines for safe practice in managing bathing waters which may produce or contain cyanobacterial cells (Chorus & Bartram 1999). Rather than providing a single threshold value, these guidelines are framed as a series of three guidelines, which reflect incremental severity and probability of adverse effects. These guidelines can be assessed using cell concentrations or cell biovolume concentrations. The later measure is preferred, as it takes into account the huge size range of cyanobacterial cells that occur in natural populations and recognises that the contribution of cyanobacterial cells to the hazard is proportional to their cell volume.

Cyanotoxins have also been demonstrated to pose serious adverse effects on mammals, birds and fish and as such are being increasingly recognised as a potent stress and health hazard factor in aquatic ecosystems. Exposure of aquatic organisms may occur both orally by uptake of toxin-contaminating cells as food, or through the surface tissues of organisms submerged in water containing dissolved cyanotoxins. Despite a growing body of evidence on the ecological effects of these compounds, there are currently no accepted guidelines for cyanobacteria and their toxins relating to the protection of aquatic ecosystems.

**Table 4.4 Outline of monitoring classes for national cyanobacterial sampling protocol (after Jones et al 2002). These are the provisional guidelines adopted by DERM.**

Monitoring class	Recommended use category	General method description	Surety of results
A1	Public health surveillance of drinking water supplies. Condition and trend monitoring—high priority water bodies	Open water sampling from boat Detailed visual surveillance (for scums) High counting precision ( $< 30\%$ counting error)	High to very high
A2	Public health surveillance of recreational water bodies. Condition and trend monitoring—moderate priority water bodies	Shoreline or bank sampling Detailed visual surveillance (for scums) High counting precision ( $< 30\%$ counting error)	High
B1	Condition and trend monitoring—moderate priority water bodies	Open water sampling from boat Low to moderate counting precision ( $> 30\%$ counting error)	Moderate to high
B2	Condition and trend monitoring—low priority water bodies. Community group monitoring	Shoreline or bank sampling Low to moderate counting precision ( $> 30\%$ counting error)	Moderate
C	Public health surveillance for scum formation in bathing waters. Community group monitoring of cyanobacterial growth	Visual surveillance only	High (for scum surveillance only) Low

#### 4.2.2.1 Storage classification

A national approach to cyanobacterial monitoring taking into account the varying needs and objectives of government agencies, councils, community groups, and members of the public was developed with the creation of a Draft National Protocol for the Monitoring of Cyanobacteria and their Toxins in Surface Waters (Jones et al 2002). It recognised a number of monitoring classes which decrease in effort and cost, and therefore precision and certainty of monitoring and analysis outcome, from that termed 'class A1' monitoring, to that termed 'class C' monitoring.

The scheme is three tiered, with each tier providing a different level of sampling and analytical precision, and overall certainty of monitoring outcome. Storage operators should determine the appropriate sampling regime based on this monitoring class classification system. A summary of the monitoring classes is given in Table 4.4.

### 4.2.3 Monitoring sites

Buoyant cyanobacteria tend to accumulate near or at the shoreline at the down wind or down stream end of reservoirs or river reaches. Therefore, for high priority public health surveillance monitoring, 'depth integrated', open water sampling is preferred. The selection of sampling sites will depend on a number of factors including prevailing winds, the position of stream inflows and the proximity to potential nutrient input sites. Open water sampling provides, in general, a better representation of the true or average cyanobacterial population of the water body. Open water or mid-stream sampling is normally carried out by operations staff working from a boat. For drinking water supplies, sampling the appropriate depth next to, or from the water off-take tower, is desirable.

In general, one open water site in the vicinity of each recreational area, and one sampling site at the water supply off-take tower, should give adequate coverage for both the water supply and recreational use health issues posed by cyanobacteria. It is desirable that both sites are marked with a buoy or similar device to ensure that sampling occurs in exactly the same area, no matter who samples.

### 4.2.4 Equipment required for algae sampling

The following equipment is required for the sampling of algae:

- integrated hose-pipe sampler—5 m length of 2.5 cm diameter plastic tubing with a weighted collar at one end (see Figure 4.10)
- a cord attached to the hose and boat
- a rubber stopper to fit one end of the tubing
- a bucket
- Lugol's iodine preservative solution
- 200 mL amber Polyethylene terephthalate (PET) plastic bottle and lid.

Figure D4.10 Procedure for use of the integrated hose-pipe sampler

## 4.2.5 Sample collection

In order to obtain a representative sample for species identification and cell count over the surface depth range, each water sample should be collected at the clearly marked sampling point using the 5 m long, 2.5 cm diameter integrated hose-pipe sampler (Figure 4.10). Sampling should be carried out in the middle of the day, preferably about 1 pm.

The procedure for collecting the sample with a hose-pipe sampler is as follows:

- Attach a cord from the boat to one end of the hose-pipe to prevent accidental loss of the equipment.
- Rinse the sampler by rapidly dropping the weighted end of the hose-pipe vertically into the water to a depth of approximately 5 m while holding the hose-pipe at the top end, and then returning the hose-pipe to the boat without inserting the rubber stopper.
- Again, while holding the hose-pipe sampler at the top end, rapidly drop the weighted end of the hose-pipe vertically into the water to a depth of approximately 5 m. This time, insert the rubber stopper into the top end of the hose-pipe after it reaches its full depth of immersion.
- Pull the bottom end of the hose-pipe to the surface using the cord, so that the tube is in a U-shape (see Figure 4.10).
- Lower the weighted end of the hose-pipe into a clean bucket and remove the rubber stopper. Ensure that the entire contents of the hose-pipe are emptied into the bucket. Mix the contents of the bucket and then transfer part of the contents into a 200 mL amber PET plastic bottle, leaving a 25 mm gap at the top of the bottle. The remainder of the contents of the bucket may be discarded.

Algal scums should not be included in the water sample for routine identification and enumeration; however, if they are present, a note should be taken indicating their nature and extent. This is particularly important in bathing or water recreation areas. Additional scum samples can be collected and submitted for qualitative analysis if extensive.

NOTE: Blue-green algae can cause skin irritation. If sampling from an area that has a high level of blue-green algae, minimise your contact with the water during sampling by wearing appropriate dress, in particular gloves. Normal hygiene precautions such as washing off any splashes and washing hands before eating or drinking should be observed at all times. When not in use, the hose-pipe sampler and bucket should be kept clean and stored in a dark shed or cupboard.

### 4.2.5.1 Sample storage and preservation

To ensure the sample remains in a condition suitable for identification and enumeration, a sufficient volume of Lugol's iodine preservative solution should be added to the sample to render the sample a colour resembling weak tea (i.e. 1.0 mL Lugol's iodine solution to 200 mL sample). Once Lugol's is added to the sample, it requires no additional treatment prior to analysis (e.g. chilling etc.). Lugol's iodine solution is made by mixing 20 g of KI with 200 mL of distilled water, and then dissolving 10 g of pure iodine in this solution. Glacial acetic acid (20 g) is added a few days before use. The solution must be stored in the dark in a glass bottle and remains effective for at least 12 months.

### 4.2.5.2 Sampling for cyanotoxin analysis

Cyanotoxin analysis will generally be required in one of the following circumstances:

- Action Level 1 status (i.e. more than 2000 cells mL<sup>-1</sup>) predominated by *Microcystis aeruginosa*, or when concentrations of other potentially toxic taxa (see Table 4.2) exceed 15 000 cells mL<sup>-1</sup>

- Action Level 2 status where numbers of a cyanobacterial taxa not previously recorded as toxic exceed 100 000 cells mL<sup>-1</sup> (recommended toxicity analysis by mouse bioassay or comparative method).

Samples for toxin analysis should be collected using the 5 m integrated hose-pipe sampler (as described in Section 4.2.5) and a 2 L chilled sample sent to the laboratory for analysis (see Appendix C6 for laboratory contact details).

In Australia, and internationally, guidelines for cyanotoxins in drinking water supplies are being set based on the concentration of toxins in water (µg toxin L<sup>-1</sup>). Hence it is recommended that for those cyanobacterial species where the toxins are well known and characterised, i.e. *Anabaena circinalis*, *Aphanizomenon ovalisporum*, *Cylindrospermopsis raciborskii* and *Microcystis aeruginosa*, routine analysis of toxins should be carried out by high performance liquid chromatography (HPLC). HPLC analysis enables the exact concentration of individual toxins in cyanobacterial samples to be quantified, with toxin concentration reported either in terms of the mass of toxin per unit mass of cyanobacteria, or mass of toxin per litre of water. Mouse bioassay should only be used if taxa other than the ones listed above are suspected of producing toxin.

#### 4.2.5.3 Sampling frequency

Monitoring class A1 and A2 storages are recommended to be sampled on a fortnightly basis, until the total blue-green algae cell count exceeds 2000 cells mL<sup>-1</sup>, after which they should be sampled weekly. Sampling can return to fortnightly after cell numbers fall below 2000 cells mL<sup>-1</sup>. Ideally, sampling frequency should be determined on a storage by storage basis using historical records of blue-green algal dynamics.

#### 4.2.5.4 Sample analysis and reporting

##### 4.2.5.4.1 Analysis precision

A suitably qualified laboratory with appropriate quality systems in place should conduct the sample analysis. When requesting the analysis it is important to state the minimum precision required of the analysis both in respect of the identification (i.e. genus or species level) and enumeration (provides the level of confidence in the result). The precision associated with the analysis of samples is directly related to the amount of analytical effort with respect to the laboratory equipment, counting effort and therefore time and staff expertise. Therefore, there is likely to be a higher cost associated with higher levels of precision. For A and B monitoring classes, it is recommended that the minimum taxonomic precision be at the genus level with species identification essential for potentially toxic species (see Table 4.2).

The counting precision is an estimation of the error associated with the estimation of abundance. It is defined as the ratio of the standard error to the mean (expressed as a percentage) for replicated counts and assumes a Poisson distribution of counting units in the counting chamber (Laslett et al 1988). The precision (counting error) can be calculated from the total number of units (n) using the formula derived by Laslett et al (1998):

$$\text{Counting error } (\pm \%) = 100 \times \sqrt{\frac{2}{\pi}}$$

Therefore the more units counted, the lower the counting error. A summary of counting errors based on this formula is shown in Table 4.5 The minimum acceptable level of precision for public health monitoring is ± 30 per cent. It is also recommended that a minimum precision of ± 30 per cent be specified for potentially toxic species.

**Table 4.5 Minimum counting error after Laslett et al (1998)**

Total units counted	Counting error ( $\pm$ %)
1	140
2	100
4	75
8	50
13	40
23	30
50	20
200	10

#### 4.2.5.4.2 Sample analysis

Sample analysis is conducted by examining a subsample under a microscope and systematically identifying and counting algal units. Specialised counting chambers of a known volume are used in conjunction with a grid system to enable examination of a known area of the chamber, and corresponding volume of sample. The two most commonly used chambers are the Sedgwick–Rafter chamber and the Lund Cell. Both are used with an upright microscope. Both are similar in that they contain a fixed volume of sample; however, the Sedgwick-Rafter chamber is etched with a calibrated grid of 50 × 20 equal sized squares (1 mm<sup>2</sup>), whereas the Lund Cell is unmarked and is used in conjunction with a Whipple Grid, which is inserted in the microscope eyepiece.

There is no Australian standard for the analysis of planktonic microalgae; subsequently, laboratories will vary slightly with respect to their preferred method. An Australian ‘benchmark’ or recommended approach for the enumeration of cyanobacteria is given in Jones et al (2002), based on the Phytoplankton Methods Manual for Australian Freshwaters (Hötzel & Croome 1999). A generic method for the identification and enumeration of planktonic microalgae using a Sedgwick-Rafter chamber based on the benchmark approach is given in Appendix H11 as an example.

#### 4.5.4.2.3 Reporting

Phytoplankton density is a concentration measure and should be reported as cells per millilitre. Algal biomass can also be reported as cell biovolume, which takes into account the contribution of species based on their relative size. Cell biovolume is measured by calculating an average volume for each species using formulae for geometrical shapes closest to the cell’s shape. The average volume for each species is then multiplied by the cell count for the species and all the products summed to gain a biovolume per sample in mm<sup>3</sup> per litre. Advice on developing a cell biovolume method can be found in APHA (1992) and Hillebrand et al (1999). Cell biovolume measurements are recommended for the calculation of recreation hazard risk after the WHO guidelines in Table 4.3.

#### **4.2.6 Contingency plan framework for blue-green algae response**

Contingency plans provide an action framework that specifies appropriate management actions in response to blue-green algal cell level thresholds. While the Queensland Water Quality Task Force created a generic action framework in 1993 (see Table 4.6), agencies operating storages are encouraged to develop site-specific contingency plans to address their particular situation.

An action level framework is a monitoring and management action sequence that water treatment operators and storage managers can use to provide a graduated response to the onset and progress of a cyanobacterial bloom. The managerial response model presented as a 'decision tree' in Figure 4.11 provides for the assessment of a potentially toxic cyanobacterial bloom, with appropriate actions and responses, through three 'threshold' stages. The action framework is based on the Australian National Alert Level scheme, and reflects recent developments in the risk assessment and monitoring of cyanobacteria released by the WHO (Chorus & Bartram 1999).

**Table 4.6 Generic contingency plan framework**

<p>Vigilance level</p> <p>Threshold definition: cyanobacterial cell numbers 500–2000 cells mL<sup>-1</sup></p>
<p>The vigilance level encompasses the early stages of bloom development, when cyanobacterial cells are first detected in unconcentrated lake or raw water samples.</p> <ul style="list-style-type: none"> <li>• When vigilance level is exceeded, it is recommended to increase the sampling frequency to at least once a week, so that potentially rapid changes in cyanobacterial biomass can be monitored.</li> <li>• Visual inspection for algal scums or accumulations of all water intakes and water recreation areas should be conducted on at least a weekly basis.</li> </ul>
<p>Action level 1</p> <p>Threshold definition: cyanobacterial cell numbers &gt; 2000 cells mL<sup>-1</sup>. Persistently high cyanobacterial cell numbers throughout the storage increasing or remaining high as per threshold definition</p>
<p>Action level 1 threshold (cyanobacterial cells &gt; 2000 cells mL<sup>-1</sup>) is derived from the WHO guideline for microcystin-LR and the highest recorded microcystin content for cyanobacterial cells. The threshold level assumes that the species present is a microcystin producer, where raw water microcystin concentration could exceed the WHO guideline value of 1 µg L<sup>-1</sup>.</p> <ul style="list-style-type: none"> <li>• If <i>Microcystis aeruginosa</i> is present at concentrations &gt; 2000 cells mL<sup>-1</sup> or other known toxin producing taxa (see Table 4.2) at &gt; 15 000 cells mL<sup>-1</sup>, the conditions require a quantitative analysis of the concentration of cyanotoxin in the raw water supply, and an assessment of whether the water treatment processes available are effective in reducing toxin concentrations to acceptable levels. Ongoing analysis of algal toxins in the raw water is necessary if values exceed 1 µg L<sup>-1</sup>.</li> <li>• Continue routine weekly monitoring of raw and treated water to ensure adequate removal of algal cells and toxins.</li> <li>• Implement use of alternative water supplies and consult health authorities if toxin concentrations in treated water exceed 1 µg L<sup>-1</sup>.</li> <li>• Visual inspection of all recreation areas should be conducted prior to entering the water – bathers should avoid contact with cyanobacterial scums. See Table 4.3 for appropriate water recreational hazard status based on latest analysis results.</li> </ul>
<p>Action level 2</p> <p>Threshold definition: cyanobacterial cell numbers &gt; 100 000 cells mL<sup>-1</sup>. Persistently high cyanobacterial cell numbers throughout the storage increasing or remaining high as per threshold definition</p>
<p>The threshold for action level 2 (cyanobacterial cells &gt; 100 000 cells mL<sup>-1</sup>) describes an established bloom with high biomass with the possibility of localised scums. Conditions in action level 2 are indicative of a significant increase in the risk of adverse health effects from the supply of water that is untreated or treated by an ineffective system or through primary contact water recreation or bathing activities.</p> <ul style="list-style-type: none"> <li>• Maintain weekly or bi-weekly sampling (depending on the dominant cyanobacterial taxa present), including all sites and visual inspection of all water recreation areas for scum formation. Ensure warning signs indicate current recreation hazard status (see Table 4.3) or direct access to storage is restricted.</li> <li>• Implement use of alternative water supplies and consult health authorities if toxin concentrations in treated water exceed 1 µg L<sup>-1</sup>.</li> </ul>

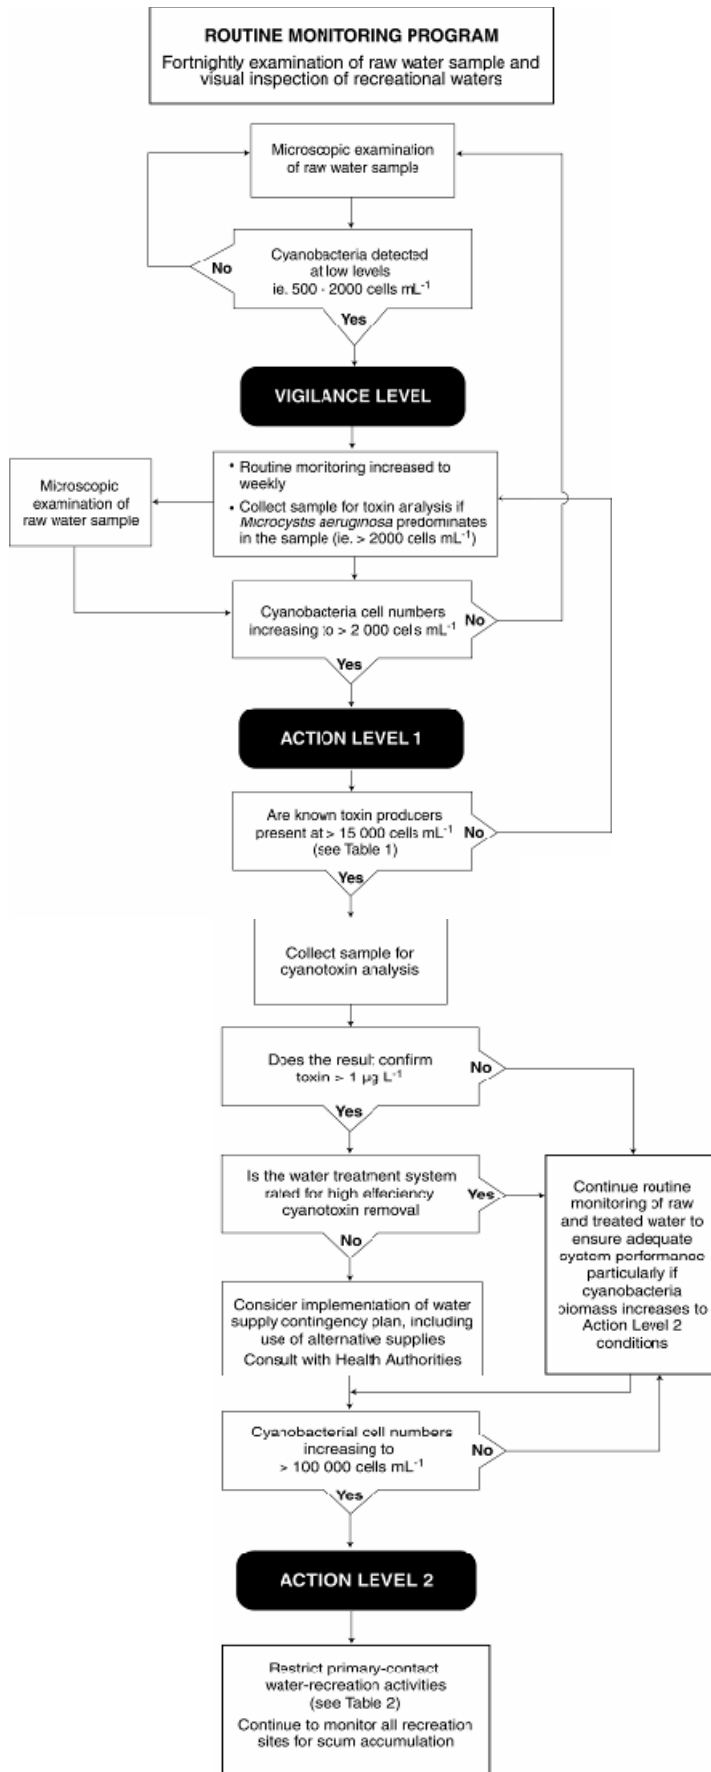

Figure 4.11 Decision tree incorporating the model action levels framework for monitoring and management of cyanobacteria in drinking and recreational waters

## 4.3 Sampling fish

### 4.3.1 General considerations

#### 4.3.1.1 Permits and approvals

A general fisheries permit is required for all work that involves 'fish' as defined in Section 5 of the *Queensland Fisheries Act 1994*. Note that early life stages such as eggs, spat or spawn of fish are considered as fish under the Act. Before undertaking any work, ensure that a General Fisheries Permit is current and covers the work outlined in the methods of fish sampling planned.

Under the Queensland *Nature Conservation Act 1992* (NCA), prior approval from the appropriate DERM work unit is required to conduct activities involving protected wildlife and places.

Under the Queensland *Animal Care and Protection Act 2001*, approval from an Animal Ethics Committee (AEC) is required for the use of animals for scientific purposes. This includes sampling of fish for scientific purposes. It is a legal obligation to receive the approval from the AEC in writing before any project can commence.

Specific procedures used to process fish will depend on the project objectives. Fish should always be handled and processed in a timely and safe manner, as specified in the animal ethics code.

**All noxious fish are to be destroyed and disposed of appropriately, and not returned to the water. Consult the Department of Employment, Economic Development and Innovation (DEEDI) for the latest information on policies and legislation regarding the release of noxious fish.**

#### 4.3.1.2 Recording fish sampling data

A fish sampling data sheet should be used to record field data. An example is at Figure 4.12.

#### 4.3.1.3 Choice of sampling method

The available methods covered in this manual are:

- fishing using drift nets
- fishing using tow nets
- fishing using small seine nets
- fishing using long seine nets
- fishing using fyke nets
- fishing using cast nets
- fishing using gill nets
- baited trap fishing
- electrofishing.

#### 4.3.2.2 Reference

Gilligan, D. & Schiller, C. (2003) Downstream transport of larval and juvenile fish in the Murray River. NSW Fisheries Final Report Series No. 50, NSW Fisheries, Narrandera.

### 4.3.3 Sampling fish using tow nets

#### 4.3.3.1 Undertaking tow

Nets are attached to an aluminium frame and fixed to the front of the boat to minimise both boat and outboard effects on the sample (see Figure 4.13).

Figure 4.13 Boat with fixed aluminium net mount and attached nets

Depending on the project purpose, different sized mesh can be used. It is recommended that invertebrates are sampled using a 250  $\mu\text{m}$  tow net, while fish larvae are sampled with a 500  $\mu\text{m}$  net. Different nets can be fixed to the opposite side of the aluminium support mount.

Depending on the project purpose, tows can be stratified according to different habitat types (e.g. open water, timbered) and three replicate tows undertaken in each. Each tow should consist of a set distance and boat speed to allow for calculation of the volume of water sampled by the nets (e.g. 40 m tow, with the boat travelling at a constant speed throughout (0.75 m/s-1) (5000 L of water)). Alternatively, the tow can be timed (2, 5, 10 or 15 minutes depending on sample area and density of organisms) and the boat kept at a constant speed. Either way, GPS readings should be taken at the start and end of the tow.

#### 4.3.3.2 Clearing nets

After the tow is completed, nets should be untied and brought back into the boat. One bucket should be filled with water to allow rinsing of any debris or animals into the base of the net. The contents of the net are then emptied into the sieve pair (i.e. coarse sieve overlying 250 $\mu\text{m}$  sieve). Finer material should be gently rinsed through the coarse sieve and then the contents of the 250 $\mu\text{m}$  sieve washed into a labelled vial for preservation. Samples will be preserved in vials using 90 per cent ethanol or methylated spirits and kept for later identification and enumeration in the laboratory.

### 4.3.4 Sampling fish using short seine nets

Seine nets primarily sample smaller fish, and larger fish are rarely encountered.

Seine nets are most effective when used in wade-able water that is no deeper than waist height.

Seine nets only sample fish that are close to the bank at the time of sampling, so will not capture species that prefer deeper water.

Very fast moving fish swim away from the net and therefore may not be sampled effectively when using this method.

It may be difficult, if not impossible, to use a short seine net in very fast flowing water.

Two people are required with one person holding each end of the net, preferably putting a foot through a foot hole in the bottom rope to assist in keeping the bottom of the net pulled taught and on the stream bed while dragging the seine through the water in order to prevent fish from escaping. The net will snag easily, so try to avoid areas of dense logs and branches.

Position one person close to the bank and the second person out in deeper water, then drag the net briskly through the water. The seine net is dragged perpendicular to the bank along a predefined length of stream (5 metres is a practical length to use). After covering this set distance, the person in deeper water should rapidly swing around to approach the bank and both people should then quickly drag the net towards the bank, through the shallows and out of the water (see Figure 4.14). Ensure that no gaps are created between the net and the streambed to prevent trapped animals from escaping underneath. If snags are encountered, stop dragging the net, free the net from the snag, and restart seining in a different stretch of stream. Speed is required when using the net; otherwise fish will easily swim clear. The seine net should be used at least three times at each site to ensure the sampling of all the different habitats available.

It is easiest to remove captured animals when the seine net is laid on the bank. The seine net should be thoroughly rinsed after all of the fish have been released.

**Figure 4.14 A seine net hauled on to the bank, enabling the removal of trapped animals**

#### **4.3.4.1 Variation to method**

A variation to this method is to seine upstream heading into a riffle, instead of seining towards the bank. Each person must then lift the edges of the net out of the water, so that the fish do not escape and carry the net towards the bank. This technique may be useful for catching species that often occur near riffles.

## 4.3.5 Sampling fish using long seine nets

### 4.3.5.1 Long seine fishing method

Long seine nets have coarse mesh; therefore, smaller fish such as *Hypseleotris* sp. are not usually sampled.

Seine nets are most effective when used in wadable water that is no deeper than waist height. See variation for deeper water at Section 4.3.5.2.

Long seine nets only sample fish that are present close to the bank at the time of sampling. Fish that only occur in deeper parts of the river may not be encountered.

Very fast moving fish may swim away from the net, and therefore may not be sampled sufficiently when using this method.

It may be difficult, if not impossible, to use a long seine net in very fast flowing water.

It takes two people to use a long seine net, one person in the water and the other person on the bank. The person on the bank holds the top and bottom rope of one end of the net. The person in the water holds the top rope of the other end of the net and puts their foot through a foot hold in the bottom rope of the net (this will assist dragging it through the water and prevent fish from escaping under the net). This person should then wade out from the bank pulling their end of the net until all of the net has been deployed into the water (see Figure 4.24). Then this person should 'loop' around towards the bank until they reach the starting point. This process should be carried out reasonably quickly; otherwise, fish will easily swim clear of the net. In flowing water ensure that the loop is started by pulling the net into the current.

Seine nets are most effective in areas where snags are not present. If snags are encountered, stop dragging the net, and free the net from the snag and restart seining in a different stretch of stream.

When the loop is complete, each person then holds the top and bottom end of their end of the net and together drag the net into the shallows and out of the water. Ensure that no gaps are created between the net and the stream bed, or else fish may escape underneath. If snags are encountered, stop dragging the net, and free the net from the snag if possible; then continue dragging the net in to shore.

It is easiest to remove fish when the seine net is laid on the bank. Rinse the seine net after all of the fish have been removed.

**Figure 4.15** A long seine net being deployed from the bank

**Figure 4.16 Fish being captured in the long seine net**

NOTE: Long seine nets will snag easily, so ensure that the net will not be dragged around logs or branches that may be visible. If snags are unavoidable restart seining in a different stretch of stream. It is easiest to use a long seine net in slow flowing water, or in water that has stopped flowing. Backwaters may be suitable for sampling at sites with high flow.

#### **4.3.5.2 Variation to method**

Where the water is too deep to wade through, the technique can be varied so that a person holds one end of the long seine at the bank and the other end is looped around by boat. However, this is not ideal, as once the water is deeper than the depth of the net, fish can potentially escape by swimming underneath. It is not recommended to 'swim' the net out if deep water is encountered. This is a slow process and will result in a low catch as fish can easily escape. It is also potentially dangerous, as the net could wrap around the swimmer's legs, causing injury or drowning.

### **4.3.6 Sampling fish using fyke nets**

#### **4.3.6.1 Fyke net fishing method**

Fyke netting is a passive method of sampling and therefore may result in some species not being sampled, rare species being common but poorly sampled, or rare species that move in schools appearing more abundant than they truly are (see Figures 4.25–4.32).

Using upstream facing fine-fyke nets during a flow event can result in the net filling with or being damaged by drifting debris. These nets should be monitored to ensure that damage is not occurring. Their use may be prohibited in areas where there are large amounts of debris.

Fyke nets are set facing downstream if the aim is to capture upstream migrating fish, or set facing upstream if the aim is to capture downstream migrating fish, drifting larvae or eggs. Net mesh size and the number of replicates should be based on the objectives of individual projects.

The nets are set at approximately 30 degrees to the bank with the wings angled out from the mouth of the net at approximately 45 degrees. The tail (cod-end) is either tied off to a tree, rock, or stake, or allowed to flow freely. A float should be placed inside the cod-end of the net and care taken to maintain an air-space so that capture of air-breathing animals (e.g. turtles) doesn't result in mortality. Once the cod-end is tied off, wade or drive the boat into deeper water with the remaining net, spreading out the inner hoops. Note that a fyke net does have a 'top' and 'bottom', with the top having floats attached to the wings and the bottom having weights

attached. Each wing should be stretched out separately (one toward the bank and one toward the deeper channel) and secured to a tree or stake. Floats on the top of the net will improve net visibility to ensure that any boats can avoid the net.

When checking the nets, pick up the first hoop. This hoop should be shaken, ensuring that any fish fall down into the next hoop. Each hoop should be shaken in turn, until all fish have been shaken down to the cod-end of the net. The tail can then be untied from its fixed position and carried to shore for sorting, or contents can be poured into a nally bin (partially filled with fresh water) in the boat.

The fyke net should be rinsed after netting has finished. Upon returning from a field trip, the nets should be thoroughly cleaned, freed of debris, hung out to dry, checked for holes and repaired if necessary before being stored.

#### 4.3.6.2 Variation to method

Ethanol may be used in place of methylated spirits to preserve samples.

Figure 4.26 Setting a fyke net

Figure 4.27 A set fyke net

Figure 4.29 A set fyke net

Figure 4.30 Opening up the tail of the fyke net to identify the captured fish

Figure 4.32 Drying fyke nets

### 4.3.7 Sampling fish using cast nets

To start, make sure the net is free of tangles and debris, and then lay it on the ground in a horizontal line away from you (see Figure 4.33). Make a loop in the draw string of the net and place it around the wrist of your throwing arm.

Figure 4.33 Cast net

Commence measuring off approximately 1 m long loops of draw string and lay them into the palm of your hand until you get to the top of the net. Next, measure off one loop of net (for a 2 m net) and lay that too in the palm of your hand. For a net 2.4 m or larger you will need to make two loops of the net

At this point (see Figure 4.34), the palm of your hand should be holding the loops approximately level with your knee to lower thigh region. Now with your left hand, grab the bottom of the net, or leadline, and place it into the palm of your right hand (which is still holding the loops). The net is now divided equally in two, either side of your right wrist.

Figure 4.34 Cast net stage 1

With your left hand (see Figure 4.35) reach over to your right hand side (with the back of your hand facing away from you) and grab the right hand side of the lead line. Place the lead line in the cradle between your thumb and forefinger and walk your fingers along the 'inside' of the net and gather about 10 handfuls of net.

**Figure 4.35 Cast net stage 2**

Next, lift this gathered handful up and place it under your right hand thumb (see Figure 4.36).

**Figure 4.36 Cast net stage 3**

Now you must gather the left hand side of the net (see Figure 4.37) by grabbing the lead line again in your left hand and holding it in the cradle between your thumb and forefinger with the back of your hand facing away from you. Gather 10 handfuls along the 'outside' of the net and hold in your left hand.

**Figure 4.37 Cast net stage 4**

To cast, hold the net like you're holding a bullfighter's cape with your right arm fully extended and parallel to the ground. Your left arm should be parallel to your right, but slightly back and lower (see Figure 4.38). Your technique will determine the equal spread of the net.

Figure 4.38 Cast net stage 5

When you throw, your feet should be firmly apart for balance, and the left foot in front of the right. The casting action is more like a flicking of your arm from the right-hand side to your left shoulder, similar to a forehand tennis shot (see Figure 4.39).

Figure 4.39 Cast net stage 5

Release the net—both hands simultaneously—about a third of the way through the cast. When your net hits the water your right hand should have met your left shoulder.

Once the net sinks to the bottom, slowly pull the draw string in towards you. This will close the net and trap the specimens.

Next, carefully retrieve the net and proceed to remove your catch and place it in a container of water drawn from the immediate area.

To preserve the life of your cast net, remove any debris from the webbing and dunk it in a bucket of fresh tap water before storing it away. Avoid leaving it out in the sun for extended periods.

### 4.3.8 Sampling fish using gill nets

The site being sampled must be first investigated to determine suitability for this type of sampling, including risk from snagging up on rocks or snags due to current. This type of sampling is not recommended in very strong flows.

It is highly recommended to use a boat for deploying gill nets. Deployment is extremely difficult without a boat, and almost impossible in deep water. Gill nets should be tied to a fixed object on the bank, and set perpendicular to the bank in still or slow-flowing water, or increasingly angled downstream with increasing flow velocity (see Figure 4.41).

One person should be dedicated to manoeuvring the boat into position. This person must hold a recreational boat licence and be proficient in operation of this type of craft/motor under the field conditions.

One person should be responsible for tying off the net onto a fixed structure (using a suitable knot to be able to be untied under load), as well as deploying the net. A net weight should be attached to the bank end of the leadline to ensure that the net does not move. As the net is deployed, the person steering the boat should slowly reverse the boat away from where the net was tied diagonally out into the current. The last section of net to be deployed should be weighted on the leadline with an anchor to prevent movement. A float should be attached to the end of the net to make it visible to other boaters, along with a flashing light if visibility is poor or at night.

Nets should be positioned within a contiguous stretch of river, and distributed so that all nets are fished as independently as possible.

The amount of time that the nets are deployed should be relatively similar for each site sampled. At 45 minute intervals, the nets should be each checked and fish removed by the best technique that facilitates loss of scales and slime (a knife can be used to cut mesh if needed).

The fish may be measured (length), identified to species level, and/or checked for condition (lesions, ulcers, flesh samples taken), and fish species abundance may be recorded. This information should be recorded onto an appropriate field sheet (see Figure 4.19 for an example). All native fish are to be released, unless they cannot be identified. In this case, representative specimens may be preserved in methylated spirits, or on ice, and stored in a labelled plastic vial/jar for later identification. Rinse the gill net after all of the fish have been released. To dry the net, tie each end to a structure. Check the net often, as birds and other animals could possibly become tangled in the net.

Figure 4.41 Setting a gill net that has been tied to one end to a snag

### 4.3.9 Baited trap fishing

Traps can come in a variety of shapes and sizes, but the most common trap is the 'funnel trap' variety (Department of Primary Industries and Fisheries, 2009). Traps can be baited or unbaited, and often a chemical light stick is added when the trap is deployed at night. Traps should be marked in accordance with permit or state fisheries legislation. Traps are mostly set from the bank, close to snags and other stream side vegetation, but they can also be set into mid stream habitats using a boat. Traps should be deployed for a standard time, into various stream habitats (including bare banks), which helps ensure the results are comparable through time. Upon retrieval, traps are emptied into a bucket of water and captured animals are processed accordingly.

### 4.3.10 Sampling fish using electrofishing

#### 4.3.10.1 Electrofishing safety

In addition to general workplace health and safety considerations, there are specific hazards associated with the use of electrofishing equipment.

The following safety material is taken from the Australian Code of Electrofishing Practice. This code should be adhered to during any electrofishing activities.

##### 4.3.10.1.1 All electrofishing

Rubber boots or waders, plus 1000V rated linesmen gloves must be worn by all electrofishing team members during operations.

Minimum of two persons are required per sampling party.

Staff training in the use of electrofishing equipment should be undertaken prior to sampling, with a senior person with more than 50 hours of electrofishing experience to be present.

Waders and long 1000V linesman gloves are to be worn when using electrofishing equipment.

Only fish nets with long (approximately 3 m for a boat) non-conductive handles are to be used for sampling.

Equipment should be regularly maintained.

No electrofishing should be undertaken within 50 m of another boat.

Electrofishing should not be conducted during wet weather or rough water conditions.

Polarized sunglasses should be worn when undertaking sampling.

#### **4.3.10.1.2 Boat electrofishing**

The boat driver must have a current boat licence and be sufficiently experienced with the size of boat being used and in the river or lake conditions present.

The boat must be adequately stable and have ample freeboard when fully loaded with gear, crew (and allow for fish catch).

Boat must be a minimum of 3.5 m long.

For boats under 4.0 m x 1.2 m, a crew of only two is allowed and maximum generator size is 5 kVA.

Anodes must be fixed to the bow and not capable of touching any part of the boat, and cables are to be channelled or clipped to boat sides to prevent tripping.

To reduce the risk of dip netter staff accidents, fixed or removable hand rails of at least 700 mm height must be fitted and non-skid flooring is recommended.

Non-slip flooring is required in the boat.

The drivers of electrofishing boats must use foot-operated deadman switches which must be operated simultaneously with boat netters, who must have either a one foot operated switch (several may be connected in parallel if more than one netter is used) or 'life-line' belt cord cut-out switches.

All lighting and ancillary electrical equipment must be extra-low voltage (less than 32VAC or less than 115VDC).

Large red DANGER warning signs must be displayed on each side of the boat.

Generators and control boxes must be fixed in position during operation.

#### **4.3.10.1.3 Backpack electrofishing**

Backpack units must meet IP 37 standards

Battery powered backpack units must use only fully sealed dry cells as a power source.

The backpack unit must incorporate a quick release harness, a deadman switch on the anode pole, and be fitted with a mercury tilt switch that cuts off power input from the battery or generator whenever the unit is tilted at more than a 45 degree angle. The tilt switch can have an automatic reset, although a manual button that can be reset by the operator is recommended. The unit must have an audible alarm when in use.

Backpack electrofishing is not recommended in water deeper than operator crotch depth.

If a backpack unit is operated from a boat, the cathode must be isolated from the boat hull. It is also recommended that two foot-pedal safety switches connected in series are incorporated.

Life jackets must be worn by backpacking crews in any dangerous situation where the water depth is greater than 0.5 m.

#### **4.3.10.2 Electrofishing method**

Backpack electrofishing is limited to water that is not deeper than the operator's crotch depth.

Boat electrofishing is limited to areas that are large enough for and accessible by boat.

The success of electrofishing is limited in highly turbid waters where dip netters find it difficult to see fish.

The location and number of shots will vary according to project requirements. The number of macrohabitats sampled (i.e. pool/run/riffle), and the number of microhabitats sampled within each macrohabitat (i.e. LWD/open water/smooth bank/complex bank), will be dependent on project requirements.

Whether sampling for targeted species or fish communities, shots should be as independent as possible.

Where possible, the location of each shot should be randomly selected at a site. These shots should not overlap, and adjacent shots should have a 10 m buffer between them.

The 'power-on' time of each shot will be project-specific; however, it must be standardised within a project. It is estimated that at least 120 seconds 'power-on' time should be achieved per shot.

Power settings do not need to be standardised, instead use the settings which maximise fish catch efficiency at each site.

##### **4.3.10.2.1 Sampling for targeted specific species or complex habitats**

Favoured habitats or areas of complex habitat (e.g. snags, root masses, undercut banks) can be specifically targeted during sampling. This type of sampling is aimed at maximising catch rather than providing a comparable 'across site' community survey. One example of applying this type of sampling is maximising the catch of golden perch for tag and release or otolith removal.

Given that time is not important to the targeted sampling approach, it is not essential to follow specific guidelines if catch per unit effort (CPUE) data are not required. However, if CPUE is to be calculated, the following guidelines should be utilised. Complex habitats should be selected and targeted, with the habitat type and total 'power-on' time spent in each habitat recorded on the data sheet. The time spent in individual habitats (see method below) will vary with success of fish catch and/or size of the complex habitat; however, keeping a record of total time is critical to the calculation of CPUE.

###### **4.3.10.2.1.1 Backpack sampling**

Electrofishing using a backpack unit is best for small, slower-flowing streams. A minimum of two people are needed, one to operate the electrofishing unit and one to collect specimens using a dip-net. Sampling should be conducted within at least 1 m of the selected habitat. Each shot should commence as the operator approaches the selected habitat, and continue while the operator walks around the habitat. A minimum distance of 3 m between habitat types should be employed to avoid influencing sampling at the next habitat.

For each complex habitat, the habitat type, total 'power-on' time and species details should be recorded.

Fish should be processed in a timely manner at the end of each complex habitat, and returned to the water.

**4.3.10.2.1.2 Boat sampling**

Teams will consist of a minimum of two people: one to operate the unit, and one to net specimens.

The boat should approach a complex habitat in such a way as to minimise access issues. Shots should commence while the boat approaches the habitat, continue while the boat is stationary or manoeuvring within the habitat, and while the boat exits the habitat, before the power is switched off. A minimum distance of approximately 5 m between sampled habitats should be employed to ensure that the previous shot does not influence the next sampled habitat.

For each complex habitat, the habitat type, total 'power-on' time and species details should be recorded. Fish should be processed in a timely manner, at regular intervals, and returned to the water.

**4.3.10.2.2 Fish community sampling**

Effort should be made to sample all habitats in approximate proportion to their occurrence at the site. Shots should be performed on alternate banks to cover all habitat types. Include mid-channel shots where necessary.

**4.3.10.2.2.1 Backpack sampling**

Electrofishing using a backpack unit is best for small, slower-flowing streams. A minimum of two people are needed, one to operate the electrofishing unit and one to collect specimens using a dip net.

The operator should attempt to thoroughly electrofish the shot area, moving in a zig-zag motion, starting from the bottom of the shot zone. The dip netter should stand downstream of the operator while dip netting fish. Nets can be set up at the upper and lower ends of a stream section to prevent movement of fish out of the sample area.

**4.3.10.2.2.2 Boat sampling**

Teams will consist of a minimum of two people: one to operate the unit, and one to net specimens.

Parallel runs with the boat travelling parallel to the bank can be carried out to capture mid-water and pelagic individuals.

Perpendicular runs can be carried out with the boat travelling perpendicular to the bank to capture individuals near the edge and associated habitats. At the completion of a shot, the details of captured fish should be recorded and the fish released.

**4.3.10.3 Data collection**

Note that when entering data into AQEIS, database field terminologies are specific. Each site requires a site number. If new site numbers are required they should only be allocated following consultation with hydrographic staff. Sample runs are multiple survey runs which are linked to a specific site on a day or within a specified date range (e.g. all shots conducted at site 123400 on 01/01/08). Samples are individual runs or shots within a sample run. AQEIS generates new sample numbers in the order of data entry but original run/shot numbers can also be retained. Specimens are the individual fish captured within a sample.

AQEIS also generates specimen numbers obtained within each sample in the order of data entry (i.e. commencing at 1 each time).

There are two EFISH sample properties templates in AQEIS, one each for boat and backpack electrofishing methods (both using Smith Root equipment). Any variables that are not collected in the field can simply be passed over when entering data. Additional variables or alternate templates can be added in by the AQEIS administrator if required. The included variables for boat fishing are shown below.

GPS Start Latitude (GDA94)	Max Sample Velocity (m/s)
GPS Start Longitude (GDA94)	Min Sample Velocity (m/s)
GPS End Latitude (GDA94)	Av Sample Velocity (m/s)
GPS End Longitude (GDA94)	Weather at Sample Time
Sample Length (from GPS)	Conductivity ( $\mu\text{s}/\text{cm}$ )
EFISH Start Time (time on)	EFISH Boat Current Mode
EFISH End Time (time off)	EFISH Boat Pulses per Second
Max Sample Depth (m)	EFISH Boat Voltage Range
Min Sample Depth (m)	EFISH Boat Percent of Range
Av Sample Depth (m)	

The template for backpack fishing is virtually the same, but the last four variables are replaced with EFISH backpack volts, EFISH backpack frequency and EFISH backpack duty cycle.

The EFISH specimen properties template in AQEIS contains the following variables.

Fish Species	
Fish Standard Length	Mm
Av Depth at which fish were caught	M
Otoliths Removed	No by default
Gonads Preserved	No by default
Stomach Contents Preserved	No by default
Fin Clips Preserved	No by default
Muscle Tissue Preserved	No by default

#### Variation to method

Additional habitat properties may also be recorded. Those found in AQEIS under the EFISH habitat properties template are as follows.

Efish Habitat Type (run/pool/rifle etc)	Efish Habitat % Macrophytes
Efish Habitat % O/head Canopy Cover	Efish Habitat % Filamentous Algae
Efish Habitat % Mud (<0.06mm)	Efish Habitat % Leaf Litter
Efish Habitat % Sand (0.06-2mm)	Efish Habitat % Overhanging Veg
Efish Habitat % F Gravel (2-16mm)	Efish Habitat % Emergent/Inundated Veg
Efish Habitat % C Gravel (16-32mm)	Efish Habitat % Root Mass
Efish Habitat % Pebble (32-64mm)	Efish Habitat % Undercut Banks
Efish Habitat % Cobble (64-128mm)	Efish Habitat % LWD
Efish Habitat % Boulder (128-512mm)	Efish Habitat % SWD
Efish Habitat % Bedrock (>512mm)	Efish Habitat % Bare

NOTE: 'EFISH' is attached to the variable names to distinguish them from existing variables relevant to other projects. 'EFISH' can also be used as a keyword when searching the database.

Project	Project Code (AQEIS)	Description of variation, rationale and any project specific variables

## Part E Preparation of aquatic animal tissues (fish and crustaceans) for veterinary laboratory examination

### 5.1 Reasons for sending aquatic animal tissues for veterinary laboratory examination

There are several reasons why aquatic animals associated with a fish kill, or other environmental health or aquaculture production problems, should be submitted to a diagnostic laboratory for examination:

- The clinical signs and gross lesions in aquatic animals may not indicate the particular disease, i.e. they are non-specific signs, and laboratory examinations are required to determine the actual cause of a disease and to then provide the diagnosis.
- A laboratory examination and laboratory testing is necessary in order to make a definitive or confirmed diagnosis in diseases where a provisional diagnosis has been made on history and clinical signs.
- It is not uncommon to have more than one agent or factor affecting aquatic animals at one time, e.g. a bacterium, a fungus and handling damage to the skin. Laboratory examinations aid the identification of primary and secondary aetiologies.
- An accurate diagnosis is often a complex process requiring the skills of several scientists who are available in the diagnostic laboratory system.
- Appropriate and responsible treatment and control of disease in aquatic animals depends on an accurate diagnosis. The negligent or unnecessary use of chemicals and antibiotics may result in chemical residues in aquaculture products for human consumption, unnecessary production costs, antibiotic resistant strains of bacteria and environmental damage.
- A wide range of environmental and/or husbandry factors influence the expression of disease, and diagnostic laboratory examinations may be required to determine the significance of infectious agents in a disease.

Many diseases in aquatic animals are a result of a complicated interaction between the animal, the environment and a pathogen or disease agent (bacteria, fungi, parasite, virus and toxins). Environmental factors (temperature, salinity, etc.) act as triggers in these situations allowing a pathogen (disease producing organism) to cause disease where it might normally be harmless (see Figure 5.1).

Figure 5.1 Disease results from the interaction of animals with environmental factors and disease organisms

Environmental factors that are involved in contributing to disease outbreaks—for example, low pH, low dissolved oxygen concentrations, pesticides and high suspended solid concentrations—can also directly affect the health of aquatic animals. This type of disease is often described as non-infectious disease.

As a consequence, it is important to determine the role and significance of both the environmental factors and the pathogens. The 'history' of the disease outbreak, site investigations and laboratory examinations are all necessary to really understand how the aquatic animals become sick.

The best way to control or prevent a disease may be the manipulation of the environmental factor(s) that make the aquatic animal susceptible to an infectious disease.

In any disease investigation, the following are needed:

- a history or details of the events leading up to and associated with the disease outbreak. This should include water quality, source of animal, stocking density, distribution of mortalities by pond or age group, feed type, and so on
- samples of both 'sick' and 'healthy' animals
- other samples may also be necessary, e.g. water, algae and feed.

## **5.2 Collecting finfish specimens for diagnostic laboratory examination**

The best samples to send to the laboratory are live finfish. Live specimens are best as they enable the pathologist to see the clinical signs, prepare gill and skin smears and are suitable for all laboratory tests (histology, bacteriology, parasitology, virology, biochemistry and toxicology).

Because finfish are in an aquatic environment and carry bacteria on the gills and in their gut, there is a rapid breakdown of tissue and decomposition after death. In most cases aquatic animals that are found dead may be of little value for veterinary laboratory examination.

### **5.2.1 Sampling live finfish**

Select a minimum of six live, sick fish with clinical signs typical of the problem. Select six normal fish for comparison. A sample from each pond, cage, tank or aquarium, or each age class or species affected in the disease outbreak should be provided. Place each group in a separate and labelled container.

Transport the live specimens to the laboratory in oxygen filled plastic bags or aerated transport tanks.

### **5.2.2 Sampling and preparing fixed finfish specimens**

Use only live finfish for fixation (fish that are found already dead are of little value for veterinary diagnosis).

Painlessly kill the finfish in an anaesthetic solution or by cutting the spinal cord behind the head.

A complete external and internal examination of the finfish should be done and the findings recorded on the specimen advice sheet to the laboratory.

Microscopic examination of wet preparations made from skin and gill smear for external parasites is essential as these parasites will leave the fish after it is placed in the fixative.

- Larval finfish: preserve 25 to 50 individuals intact

- Small finfish (less than 4 cm in length): cut open the abdominal cavity, move the swim bladder and visceral mass away from the caudal kidney, and place in fixative
- Large finfish (more than 4 cm in length): the individual organs should be removed, sectioned and placed in fixative. Tissues to sample include the gills, heart, liver, spleen, head kidney, caudal kidney, digestive tract (intestine), eye, skin, muscle, brain, swim bladder and any other organ or tissue with lesions. Tissue pieces should be about 15 x 15 mm and no thicker than 8 mm.

Place the tissues in chilled fixative if possible. There must be at least 10 times more fixative volume than tissue volume. After 24 to 48 hours, the fixed tissues can be wrapped in fixative-moistened paper towels, placed in two sealed plastic bags and sent to the laboratory.

The fixatives used include 10 per cent formal saline (for marine specimens), 10 per cent buffered neutral formalin (for fresh and brackish water specimens), and Bouin's solution (has the advantage of rapid preservation).

NOTE: Fixed specimens are only suitable for pathology and histopathology (not chemical analysis).

### 5.2.3 Freshly killed finfish on ice

Fish on ice are only of use for bacteriology, virology and toxicology. If you submit freshly killed fish on ice, they must be accompanied by a submission of fixed specimens.

Finfish are painlessly killed with an anaesthetic, wrapped and sealed in a plastic bag, and placed in an excess of crushed ice.

The delay between sampling the finfish and arrival at the laboratory should be no longer than 24 hours.

NOTE: Freshly killed finfish on ice are only suitable for bacteriology and internal parasite examination, although they can be used for virology, toxicology and histopathology if necessary.

### 5.2.4 Frozen finfish

These specimens are only suitable for toxicology and virology. Specific suspect toxin(s) (e.g. pesticides) need to be nominated before laboratory analysis will be done.

### 5.2.5 Fixatives and anaesthetics

Have plenty of fixative on hand, as you need at least 10 times the volume of fixative for each volume of tissue or finfish.

#### 5.2.5.1 Fixatives

10 per cent formal saline (for marine specimens):

- formalin (37–40 per cent w/v formaldehyde solution)—100 mL
- saline solution (0.73 per cent, 73 gm salt per 10 L water)—900 mL

(Saline solution may be replaced with seawater for marine finfish.)

NOTE: formalin is a skin and respiratory irritant, and care must be taken when using it.

10 per cent buffered neutral formalin (for fresh and brackish water specimens):

- formalin (37–40 per cent w/v formaldehyde solution)—100 mL
- tap or distilled water—900 mL

- disodium hydrogen phosphate  $\text{Na}_2\text{HPO}_4 \cdot 2\text{H}_2\text{O}$ —6.5 grams
- sodium dihydrogen phosphate  $\text{NaH}_2\text{PO}_4 \cdot 2\text{H}_2\text{O}$ —4.5 grams

NOTE: formalin is a skin and respiratory irritant, and care must be taken when using it.

Bouin's solution:

- saturated aqueous picric acid—750 mL
- formalin (37–40% w/v formaldehyde solution)—250 mL
- glacial acetic acid—50 mL

NOTE: Specimens must be transferred from Bouin's solution to 70 per cent ethanol (ethyl alcohol) after 24 hours. Store tissues in 70 per cent ethanol.

NOTE: Dry picric acid is explosive. Use extreme care with storage and handling.

Davidson's solution:

- glacial acetic acid—115 mL
- formalin (37–40 per cent w/v formaldehyde solution)—220 mL
- 95 per cent ethyl alcohol (ethanol)—330 mL
- tap or distilled water—335 mL

NOTE: Once specimens have been fixed in Davidson's solution for 24 to 72 hours they must be transferred to 50–70 per cent ethanol. The fixed tissue is then stored in 50–70 per cent ethanol.

#### 5.2.5.2 Anaesthetics for euthanasia

MS 222 (Tricaine methanesulphonate; ethyl m-aminobenzoate; 3-aminobenzoic acid ethyl ester) 1 gram per litre of water. This concentration is lethal in 5 to 10 minutes.

Benzocaine (Ethyl p-aminobenzoate; 4-aminobenzoic acid ethyl ester):

- Benzocaine is not soluble in water and a concentrated stock solution should be made up.
- Dissolve 50 grams of benzocaine in 500 mL of 95 per cent ethanol (100g/L). If stored in a dark bottle the stock solution will keep for at least a year.

NOTE: 10 mL of benzocaine stock solution per litre of water (10/L) is lethal in 5 to 10 minutes.

Benzocaine is less expensive to use than MS 222.

AQUI-S (2-methoxy-4-propenyl phenol)

A two stage process is suggested when using AQUI-S for anaesthesia and humane death:

- Stage 1: use 25 to 30 ppm to induce heavy sedation (i.e. no gill movement, no cough reflex on forced extension of the operculum)
- Stage 2: humanely kill the fish by pithing.

NOTE: All chemical anaesthetics must be prescribed by a veterinarian for use in food fish.

#### 5.2.6 Basic anatomy of finfish

Actual details of finfish anatomy may vary from species to species. The generalised diagrams and the photographs given below indicate the general location of organs (see Figures 5.2 and 5.3).

Figure 5.2 External anatomy of a finfish.

Figure 5.3 Internal anatomy of a finfish.

### 5.2.7 Gill and skin smears and wet mounts

Microscopic examination of mucus and surface cells from skin and gill scrapings is the best way to find external parasites. External parasites will fall off or leave the host during transport, after death or after fixation, so it is important that only freshly dead finfish are used for preparation of smears. Smears should be examined before specimen fixation.

#### 5.2.7.1 Method for preparing gill smears and wet mounts for finfish

- Painlessly kill the fish by cutting the spinal cord behind the head.
- Remove a gill arch, place on a clean glass microscope slide and gently scrape mucus off the gill filaments with a clean scalpel blade onto the clean glass microscope slide (see Figure 5.4 (3)).

- Gently scrape the skin, particularly areas at the base of pectoral and pelvic fins, with a clean scalpel blade and place the mucus on a clean glass microscope slide. Scales should not be removed when preparing skin smears (scrape in the direction of the scales) (Figure 5.4 (4)).
- Add a drop of water that the fish were swimming in and gently mix (see Figure 5.5).
- Cover with a cover slip (Figure 5.5). Try and avoid trapping air bubbles.
- Examine under a microscope using a low-power objective (either 10x or 20x). Examine smears as soon as possible as the movement of living parasites greatly aids detection. Do not let the wet preparation smear dry out, as the parasites will die quickly.

Figure 5.4 Preparing a skin and gill smear

### 5.2.7.2 Important points concerning smears and wet mounts

Any cysts or nodular structures found during external or internal examination can be removed, squashed or teased apart, wet mounted and examined in the same way that gill/skin smears are prepared.

At times it can be useful to cut off entire gill filaments and wet mount them for microscopic examination. Again, external parasites will be apparent and some indication of gill damage is seen by studying the filament and lamellar structure. In the case of bacterial gill disease, bacteria and areas of hyperplasia and necrosis will be seen.

Figure 5.5 Preparing a skin and gill smear

## 5.2.8 Finfish dissection

The basic method of finfish dissection involves three or four cuts (see Figure 5.6):

1. Lay the fish flat on one side with the dorsal fin facing away from you.
2. Lift the operculum (gill cover) and cut it off being careful not to damage the gills (cut 1).
3. Make a small cut with scissors or a scalpel blade just in front of the anus (vent) to open the abdominal cavity. Avoid cutting the lower intestine or damaging any abdominal organs when you do this.
4. With blunt ended scissors, cut along the ventral midline forward from the small cut to between the jaw (cut 2).
5. Remove the flap of skin covering the abdominal cavity by cutting from the small cut upwards and forwards (cut 3). The heart and all the abdominal organs should be exposed for examination and removal (see Figures 5.7 and 5.8).
6. If the brain is to be examined, remove the top of the head with several shallow slices using a scalpel blade, cutting from just behind the eyes towards the front (cut 4). Alternatively, the whole head can be removed; place the cut end down and make the slice downwards towards the dissection board. This can be done if the fish is young and the skull is not too hard. In older fish, bone cutters or saws will need to be used.

Figure 5.6 Partial dissection of a finfish using four cuts

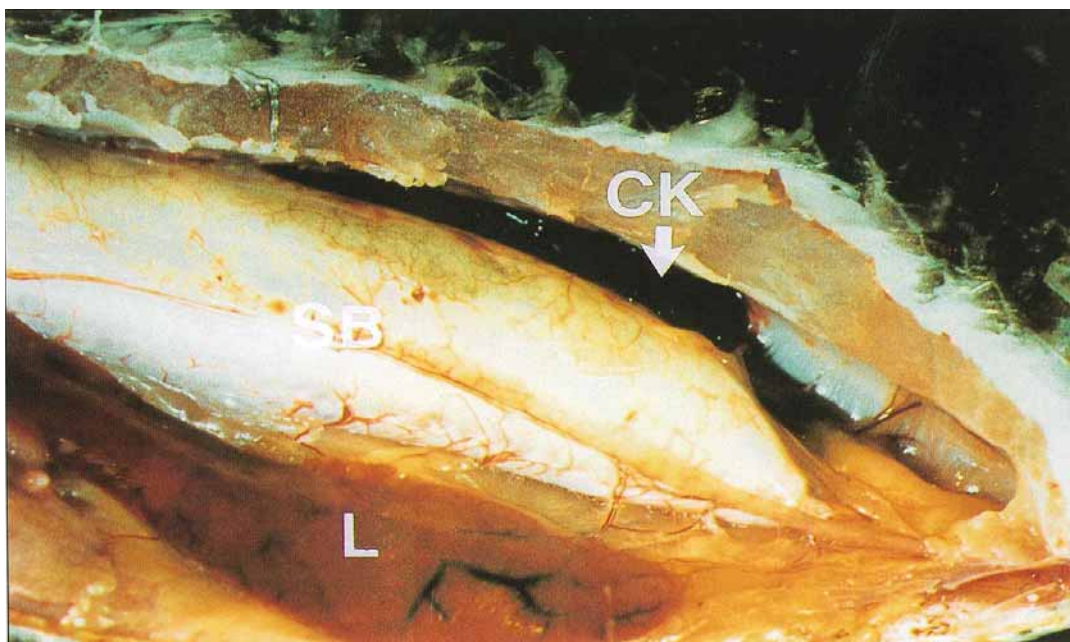

Figure 5.7 The internal anatomy of a dissected finfish. AF = abdominal fat, G = gills, H = heart, HK = head kidney, L = liver, PC = pyloric caecae, S = stomach, SB = swim bladder

**Figure 5.8** The internal anatomy of a dissected finfish. This photograph shows the location of the caudal kidney (CK) which is exposed when the swim bladder is deflected ventrally. The caudal kidney lies against the vertebral column and runs the length of the abdominal cavity, L = liver. SB = swim bladder

### **5.3 Collecting crustacean specimens for diagnostic laboratory examination**

The crustacea include prawns, crayfish and crabs.

Prawns, crabs and crayfish decompose very rapidly after death. Only live or freshly fixed specimens are useful for veterinary laboratory examinations. The hepatopancreas (digestive organ), which is important in the diagnosis of many diseases, decomposes extremely quickly and special care needs to be taken to ensure it is preserved correctly.

#### **5.3.1 Sampling live crustacea**

The best samples to send to the laboratory are live samples. Live specimens are preferred as they enable the pathologist to see the clinical signs and prepare gill wet mounts, and are suitable for all laboratory tests (histology, bacteriology, parasitology and toxicology). Transport the live specimens to the laboratory in oxygen filled plastic bags or aerated transport tanks (see section H).

Select a minimum of six live, sick animals with clinical signs typical of the problem. Select six normal animals for comparison. A sample from each pond, cage, tank or aquarium, or each age class or species affected in the disease outbreak should be provided. Place each group in a separate and labelled container.

For larval and early post-larval crustaceans (less than 10 mm) or crab-1 etc, sample 50 larvae or post-larvae from each rearing or nursery tank, or age class or species affected by disease or mortality.

For juveniles (more than 10 mm long) and adult prawns or crabs, select a minimum of six live, sick animals with clinical signs typical of the problem together with six normal animals for comparison. A sample from each pond, pool, or tank, or age class or species affected in the disease outbreak should be provided.

### 5.3.2 Sampling fixed specimens

If it is too difficult to transport the specimens alive, the only alternative is to send fixed specimens. Fixed specimens are suitable for pathology and histopathology.

Use only five crustacea for fixation.

Juveniles and adults can be anaesthetised by chilling in a freezer. Do not freeze them.

A microscopic examination of larvae or post-larvae, and external and internal examinations of juvenile and adult crustacean, should be done and the findings recorded on a note to the laboratory.

Examination of wet preparations of gill filaments and appendages for attached organisms or abnormalities should be done if necessary before fixation.

### 5.3.3 Basic anatomy of crustacea

Before embarking with specimen fixation, familiarise yourself with the general anatomy of the species you are dealing with (see Figures 5.9 – 5.12).

**Figure 5.9 External anatomy of a prawn.** A=antenna, AB=abdominal segment, AC = adostral carina, AF = antenna flagellum, AS = antenna scale, E = eyestalk, HS = hepatic spine, P = pereiopods, P1 = pleopods, R = rostrum, SAS = sixth abdominal segment, T = telson, TM = third maxilliped, U = uropod

**Figure 5.10 Internal anatomy of a prawn.** FC = foregut chambers, Ha = haemocoel, H = heart, HG = hind gut, MG = mid gut, MGG = mid gut gland, O = ovary, VNC = ventral nerve cord.

**Figure 5.11 External anatomy of a crab.** A = antenna, AB = abdomen, DG = digestive gland, E = eye, SL = swimming leg, WL = walking leg

**Figure 5.12 Internal anatomy of a crab.** AG= antennal gland, DG = digestive gland, E = eye, H = heart, HG = hind gut, M = mid gut, O = oesophagus, S = stomach, SG = supraoesophageal ganglion, TG = thoracic gland, VNC = ventral nerve cord

### 5.3.4 Sampling and preparing fixed crustacean specimens

#### 5.3.4.1 Dissecting prawns and crayfish

The method of prawn and crayfish dissection varies according to the size of the animal:

- Larvae and post-larvae less than 10 mm (1 cm) in length (or crab-1):
  - Catch 25 to 50 individuals with a plankton mesh net and place whole into a bottle of fixative solution, either 10 per cent formalin or Davidson's solution.
- Prawns or crayfish 10 mm to 30 mm in length:
  - Cut between the thorax (head) and abdomen (tail) and place in fixative.
- Crabs 10 mm to 30 mm:
  - Cut open the top carapace (shell) of the crab and place whole animal in fixative.
- Prawns or crayfish greater than 30 mm in length:
  - Draw up Davidson's solution into a syringe. Attach a needle (e.g. 21 gauge). Hold prawn firmly with head facing away from you. Inject 0.5 to 2.0 mL of fixative (depending on the size of the prawn) at a 45 degree angle into the head, aiming for the hepatopancreas.
  - Reposition the needle so it is pointing towards the tail and inject 1.0 to 2.0 mL of Davidson's solution into the abdominal muscle.

- Remove the thorax (head) from the abdomen (tail) by slicing between the head and tail using scissors.
- Cut along the dorsal surface (top) of the head, just underneath the carapace (shell) from the end of the head carapace right up to the rostrum. Take care not to damage the heart or stomach which lie directly beneath the shell of the head.
- Turn the prawn over and cut along the ventral (bottom) side along the midline thoracic carapace between the walking legs.
- Cut out a segment of abdomen, the thickness of one abdominal segment and place into the bottle of fixative (see Figure 5.13).

NOTE: Davidson's solution is a harsh chemical mixture and precautions should be taken to avoid skin and eye contact.

Figure 5.13 Steps in the dissection of a prawn or crayfish

### 5.3.4.2 Dissecting crabs

The method of crab dissection is as follows:

- Make two longitudinal cuts with a small hacksaw from the posterior (back) edge of the carapace (shell) adjacent to the swimming legs to the anterior (front) edge of the carapace just lateral to the eye stalks (see Figure 5.14).
- Cut across the carapace from right to left swimming legs, joining the two longitudinal cuts.
- Remove the piece of dorsal carapace. When lifting the carapace, carefully dissect away muscles and tissue attachments on the inside of the carapace.
- Twist off one lateral edge of the carapace to expose the gills on that side. Remove the digestive organ contained in this lateral carapace for fixation.
- The heart and thoracic organs should be exposed for examination and removal. The thoracic ganglion and antennal gland are only visible after the stomach, heart and digestive gland are removed.

Figure 5.14 Steps to the dissection of a crab.

### 5.3.4.3 Important points concerning fixation of crustaceans

The fixative of choice for crustaceans is Davidson's solution.

If Davidson's solution is not available, 10 per cent formalin (formal saline or buffered neutral formalin) (see section 3.5.4) can be used as a poor alternative (do not transfer to ethanol).

There must be at least 10 times more fixative volume than tissue volume. After 24 to 72 hours the fixed tissues should be removed from the fixative solution, rinsed in tap water and transferred for storage in 50–70 per cent ethanol.

If possible place the tissues in chilled fixative as it will increase the time available for the chemicals to penetrate the cells, prior to decomposition.

Fixed specimens can be sent to the laboratory by wrapping in paper towels moistened with 50–70 per cent ethanol and sealing in two plastic bags.

Frozen crustaceans are only suitable for toxicology or virology. The history must indicate toxicoses and specific suspect toxin(s) must be nominated before laboratory analysis will be done.

### 5.3.5 Gill, appendage and larval wet mount preparations

Microscopic examination of gill clips and the tips or appendage outgrowths is the best way to detect ectocommensals, ectoparasites and excessive debris. Larval crustacea are small and many lesions and tissue changes can be missed when they are examined histologically. Gut contents, heart and gut activity, bacteria, fungi, protozoans and lesions are more easily assessed when larvae are examined microscopically in wet mount preparations.

#### 5.3.5.1 Method for preparing gill smears and wet mounts for crustaceans

Remove the gill cover with scissors, cut off a gill filament and place on a clean glass microscope slide (see Figure 5.15). Remove appendage tips or outgrowths and place on a glass slide. Collect a group of larvae by filtration or pipette and place on a glass slide.

Add a drop of water (water that the crustacean was swimming in) or saline solution on to the glass slide.

Cover with a cover slip and avoid trapping air bubbles.

Examine under a microscope using a low-power objective (either 10x or 20x). Do not let the wet preparation dry out (add more water with a pipette), or the crustacean larvae and protozoa will die quickly.

Examination of larvae should cover 10 areas: eye surface, antennae, rostrum, gut content, midgut movement and size, gill area, walking legs (pereiopods), swimming legs (pleopods), tail (telson and uropods), and general pigmentation (see Figure 5.16).

Figure 5.15 Preparing a gill mount from a prawn

Figure 5.16 Points of a prawn larvae to examine

### 5.3.6 Sampling and preparing molluscs

Oysters and clams decompose very rapidly after death. Only live or freshly fixed specimens are used for diagnostic laboratory examination (see Figures 5.17–5.19).

#### 5.3.6.1 Live molluscs

- Larvae and spat (or post-settlement stages):
  - Sample 50 larvae or spat from each rearing or nursery tank/pool/pond or age class or species affected by disease or mortality.
- Juveniles and adults:
  - Select a minimum of six live, sick animals with clinical signs typical of the problem together with six normal animals for comparison. A sample from each raft, rack area or tank, or age class or species affected in the disease outbreak should be provided.
- Transport the live specimens to the laboratory in oxygen filled plastic bags (larvae) or wrapped in damp paper towels or cloth in an insulated container.

NOTE: Live specimens are preferred as they enable the pathologist to see the gross clinical signs and prepare gill and wet mounts, and are suitable for all laboratory tests (histology, parasitology, bacteriology and toxicology).

#### 5.3.6.2 Fixed mollusc specimens

- Select only five molluscs for fixation.
- Juveniles and adults: these can be anaesthetised by chilling or by placing them in magnesium chloride or propylene phenoxetol solution.
- A microscopic examination of larval molluscs should be done and the findings recorded on a note to the laboratory.
- Larvae and post-settlement stages less than 10 mm shell length: preserve 25 to 50 individuals intact.
- Oysters greater than 10 mm shell length: cut open the two valves, remove the soft organs from the shell and place in fixative. Cut the visceral mass into pieces no thicker than 8 mm if necessary, before fixation.
- Clams up to 10 cm shell length: remove the two valves by cutting the mantle and adductor muscle attachments, and place in fixative.
- Clams greater than 10 cm shell length: remove the valves, dissect out individual organs. Tissues to take include the gills, digestive gland, mantle, kidney, muscle, heart, gonad and any other organ or tissue with lesions.

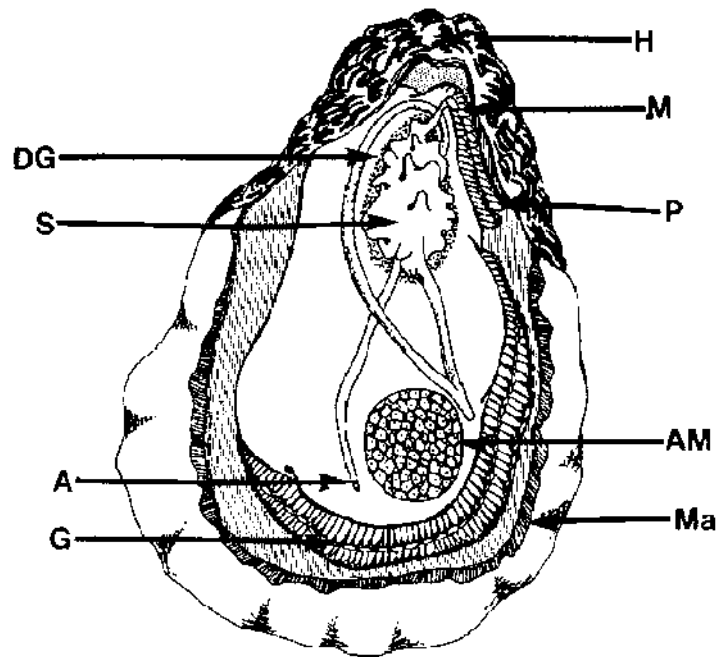

- Pearl oysters up to 10 cm shell length: cut open the two valves, and remove and preserve all the soft organs as a group. A shallow cut may be made on one side of the organs to allow the fixative to enter more rapidly.
- Pearl oysters greater than 10 cm shell length: cut the oyster in half by making a parallel cut between the two shell valves. Remove the two halves of oyster tissue and place in fixative. If there is too much tissue, place each half in a separate container which is labelled so that both halves can be identified to the one pearl oyster.
- If possible place the tissues in chilled fixative as this will slow decomposition before the chemicals have a chance to penetrate the mollusc cells.
- Fixed specimens can then be sent to the laboratory by wrapping in paper towels moistened with fixative or 50–70 per cent ethanol (whichever is appropriate) and sealing in two plastic bags.
- The fixatives used include 10 per cent formal saline and Davidson's solution.

NOTE: Fixed specimens are only suitable for pathology and histopathology.

## Part F Monitoring mangrove forest health

NOTE: In Queensland, mangrove and other marine vegetation is protected under the *Fisheries Act 1994*. Permits are required from Queensland Primary Industries and Fisheries (QPIF, under the Department of Employment, Economic Development and Innovation) to remove, destroy or damage a marine plant; or cause a marine plant to be removed, destroyed or damaged. Therefore, persons monitoring in this environment and requiring the removal of any mangrove matter from the field should contact their local office of the QPIF for further information.

### 6.1 Mangrove litter trapping

#### 6.1.1 Introduction—what is litter and how is it related to mangrove forest health?

Mangrove litter production is the shedding of vegetative and reproductive structures of mangroves (e.g. leaves and seeds). This may be caused by natural growth cycles, age, stress and/or mechanical factors, such as wind. This litter fall, part of the net primary productivity of a mangrove system, is the basis of detritus food chains.

The rate of litter production can indicate the health of a mangrove community. A healthy system will produce a high and/or stable monthly volume as older leaves are shed and replaced with new ones. Declining production may indicate that a community is under stress. The amount of reproductive material can also be used as a measure of health, as reproduction effort can be considerably reduced if plants are stressed.

The ratio of fallen leaves to stipules of *Rhizophora* spp. can also be used as an indicator of system health. Every developing leaf is enclosed in a stipule, which is shed when the leaf matures. Thus, in a healthy community, the ratio of leaves to stipules in the litter should be close to 1:1. If there are more leaves than stipules, this may indicate that the plant is shedding leaves due to stress.

A significant decline in leaf and flower production outside seasonal variations may indicate that a mangrove community is under stress.

#### 6.1.2 Why monitor litter productivity?

The main reasons for monitoring litter productivity are to:

- gain an understanding of the baseline litter productivity of a mangrove community
- indicate system health—litter fall is a useful indicator of this as mangrove communities under stress are likely to be less productive, resulting in less litter production over time. Alternatively, communities under stress produce a large amount of litter over a short time as the plants shed leaves
- look at unseasonably low litter production due to poor growth resulting in less detritus, and this may adversely affect faunal communities.

#### 6.1.3 Method summary

Leaf litter traps are installed in a mangrove community. Litter is collected monthly, sorted into different categories (leaves, twig, bark, flowers and propagules), oven dried, and weighed. The dry weight is a measure of the productivity of the community. Problems to be aware of include: significant disturbances (e.g. cyclones) may damage sites and make it necessary to begin collecting data again for a time series; traps can be interfered with by others; and climatic and biological differences in Australian mangroves make it difficult to compare data from different locations.

If a storm has damaged a site and stripped many of the leaves, litter should not be collected. Instead, traps should be emptied and checked for damage. Monitoring can recommence, but a new starting date will have to be noted. As leaf loss is normally balanced with leaf production, a 1:1 ratio is the most useful indicator of mangrove health.

Leaf litter traps can be constructed from PVC pipe and plastic mesh as illustrated in Figure 6.1.

Figure 6.1 How to make a litter trap

#### 6.1.4 Site selection

Survey the mangrove community and identify the different forest types or zones that occur. Depending on the objectives of your program, select a homogenous forest type to monitor. Within this forest, put litter traps at 5 m intervals along a transect running parallel to the tidal gradient. Alternatively, put them at random in large quadrats (e.g. 10 m x 10 m, 20 m x 20 m, etc.).

#### 6.1.5 Installing litter traps

Install litter traps by attaching nylon cord to each corner of the trap and hanging them evenly from mangrove branches. Ensure that the bottom of the trap or chute is above the high tide mark (see Figure 6.2).

### 6.1.6 Emptying the traps

Traps should be emptied every month (every two weeks if measuring *Avicennia marina*) to prevent leaf decay and to determine monthly trends. To empty a trap, remove any large sticks and put them in a plastic bag marked with the trap number. Put the bag under the chute, untie the chute and empty the trap contents. Re-tie the chute securely and proceed to the next trap.

### 6.1.7 Sorting trap contents

On returning from the field, sort contents into leaves, flowers, bark (include wood), seeds, other and, if monitoring in a *Rhizophora* forest, stipules. Do not mix the litter contents from different traps. Count the number of leaves and stipules and record the result. Place the sorted contents into smaller, labelled paper bags, and then put the datasheet and smaller bags in the large labelled plastic bag for transport to the drying ovens.

Note: Leaf litter contents can be kept in a refrigerator for up to a week before being dried.

### 6.1.8 Dry and weigh trap contents

- Dry the labelled paper bags in a drying oven at 70°C for 72 hours.
- Using laboratory scales, weigh the contents from each category in each trap separately. Record the results (in grams, to three decimal places). If there is insect damage, leaf dry weight is likely to be low, biasing estimation of leaf productivity. Therefore, leaf loss needs to be quantified by sorting leaves from each trap into the closest matching category as detailed in Table 6.1 and Figures 6.2 and 6.3.

For example, if a leaf is about 40 per cent intact, put it in the '50% remaining' category; classify a leaf with 90 per cent remaining as a 'full leaf'. Weigh material in each percentage loss category, and correct for damage using the formulas provided. The sum of the corrected weights of leaves in all categories is the weight of leaves for the trap. Record this result on the datasheet for each trap.

**Table 6.1 Percentage loss categories of mangrove leaves**

Category of leaf loss	Measured weight	Correction factor	Corrected weight
Full leaf		None (as measured)	
75% remaining		Multiply by 1.333	
50% remaining		Multiply by 2	
25% remaining		Multiply by 4	
			<b>Total =</b>

Figure 6.2 A litter trap in a mangrove forest

Figure 6.3 Leaf percentage loss

### 6.1.9 Data interpretation

Data is interpreted as mean dry weight of litter fall per square metre, per month, expressed as g/m<sup>2</sup>/month. Ranges and standard deviations between traps should also be calculated.

Mangrove communities exhibit strong seasonal, annual and temporal variations in litter production, with peak fall occurring in summer in most locations, and varying with climatic conditions from year to year. It will also vary between regions due to different climate, rainfall, salinity and nutrient availability. For example, mangroves in the wet tropics are likely to produce more litter than those in more temperate climates. As different species also produce litter at varying rates, it is not usually appropriate to compare results between different regions and species.

Significant decline in leaf litter fall or reproductive effort in a particular mangrove community may indicate that it is under stress, so seek advice from relevant experts if such trends occur. If soil salinity is also being monitored, check data to see if unusual levels (high ones, in particular) have been recorded.

If comparing the stipules to leaves ratio in communities of *Rhizophora* spp., the ratio should normally be close to 1:1. Trends showing a higher ratio of leaves to stipules may indicate that the plants are shedding leaves, indicating possible stress.

For analysis of trends, data should be collected for at least three years, as some species of mangroves produce propagules every 2–3 years only.

## 6.2 Seedling regeneration

### 6.2.1 Introduction—why monitor mangrove seedlings?

Due to their intolerance to shade, seedlings of most mangrove species are absent, or in low densities, under a mature forest canopy. However, the death of mature trees leaves a gap in the canopy, allowing increased light to reach the forest floor, and triggering the establishment of seedlings. These rapidly colonise the light gap, beginning the process of regeneration and eventually refilling it. These seedlings can be more susceptible to environmental stress than mature mangroves are. A heavy deposition of sediment from an event or major changes to site hydrology can induce stress, resulting in decreased growth rates and increased mortality.

Light gap regeneration rate can be an indicator of mangrove system health. Seedlings respond to environmental changes more rapidly than mature stands do, and monitoring can produce useful data in as little as three months, which is the normal monitoring frequency.

Long-term hydrological changes, such as sediment deposition or greater tidal and freshwater influence, may have occurred at the site over the past 10–30 years, resulting in colonisation by a different species from the original. For example, long-term sediment deposition may raise the elevation of a site, resulting in conditions more favourable for species normally found higher up the tidal gradient. Other hydrological changes, resulting in more tidal or freshwater influence, could create conditions favouring species normally found closer to the seaward or landward margin. Identifying what species of mangrove is replacing the previous forest can indicate whether climatic or hydrological changes have occurred.

### 6.2.2 Method summary

In a light gap or a recovering mangrove forest, a belt transect containing a minimum of 25 mangrove seedlings is established. The height and stem diameter of each seedling within the transect is monitored every three months and is used to calculate the approximate trunk volume of the seedling.

### 6.2.3 Site selection

When selecting a site, use recent aerial photographs or local knowledge to find canopy or light gaps in a mangrove forest, and confirm that there are seedlings present by ground truthing. At least four light gaps from one homogenous mangrove community are required for data interpretation.

### 6.2.4 Establishing a belt transect

To establish a belt transect running north-south through the middle of a light gap:

- Walk to the middle of the gap and take bearings directly to the north and south.

- Mark with stakes the spots where the north-south bearings intercept the boundary of the gap. These will be the start and end points of the transect.
- Starting at the northern point, lay out the 50 m tape measure through the middle of the gap, to the southern boundary (see Figure 6.4)
- Record the length of the transect on the datasheet.

The transect needs to be wide enough to include at least 25 seedlings within its boundaries. Start with one that is 2 m wide (1 m either side of the tape measure), and count the number of seedlings. Increase or decrease the distance until a suitable width, containing an adequate number of seedlings, is established. Record this width on the datasheet.

If seedlings are extremely dense, establish four quadrats, each with 25 or fewer seedlings at regular intervals along the transect. The seedling density determines the size of the quadrats, but all must be equal. If seedlings are sparse (less than 50 in the entire gap), or if the light gap is small, sample the entire gap.

Note: This method is a general approach to establishing a monitoring plot that will compensate for uneven light distribution in most instances. However, a belt transect may not always be suitable, and the dimensions of a suitable monitoring plot should be established case by case.

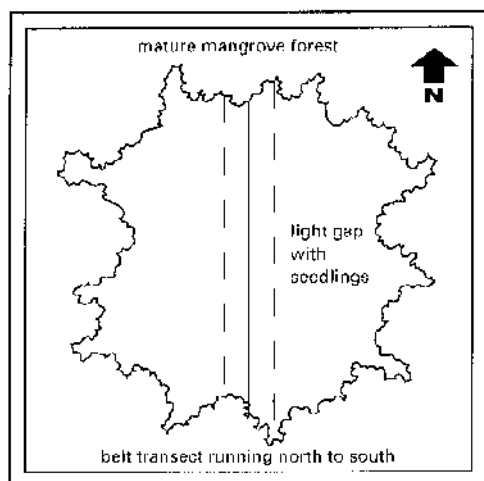

Figure 6.4 Belt transects can be established through a light gap running north to south

### 6.2.5 Tag seedlings

Using flagging tape, tag each seedling along the transect with a unique number. Beside the corresponding number on the datasheet, record the distance of each seedling along the transect and its position (distance to the left or right) from the middle of the transect (e.g. 12 m, left 0.7 m). This allows for easy location of the seedlings during repeat surveys.

### 6.2.6 Measure height

Using the measuring stick, record the height of the seedling by measuring from the ground to the base of the uppermost apical shoot. If the seedling is growing from a propagule, take the measurement from just above (see Figure 6.5). Record the result on the datasheet.

### 6.2.7 Measure stem diameter and stem density

Using plastic calipers, measure the stem diameter of the seedling at the base of the cotyledon, which is just above the original propagule. If there is no propagule, take the measurement at the base of the stem, just above the swelling.

Density (number of stems per m<sup>2</sup>) is also recorded. As the light gap matures, density is likely to decrease naturally, as many of the seedlings die due to competition.

Figure 6.5 Where to take stem diameter and height measurement

### 6.2.8 Count the leaves

Count the number of leaves on each seedling. If there are more than 25, record the result as more than 25 leaves.

Leaf counts provide an indicator of seedling progress in the early stages of development. However, after 25 leaves have established this becomes very time consuming.

### 6.2.9 Record sediment type, pH and salinity

Collect a sample of the substrate at the middle of the transect and rub it between your fingers. Record the sediment type (silt, fine sand, sand, coarse sand, or gravel) based on its feel, listing the dominant type first (i.e. record a silty sand as sand/silt).

It is also advisable to record the salinity and pH of the sediment within the transect.

### 6.2.10 Draw a mud map of the site

Draw a mud map of the gap showing its dimensions, an arrow representing north, the position of the transect, and the surrounding forest type.

### 6.2.11 Measurements needed during re-survey

When the site is re-surveyed, the death of any seedling should be recorded beside its unique number. New seedlings should be assigned new numbers (do not reassign numbers from dead seedlings) and their height, stem diameter and leaf number recorded.

As seedling density decreases, the size of the study area will have to be increased to retain 25 plants (e.g. by increasing the width of the belt transect). When the stem diameter is greater than 2.5 cm, measure the stem at a height of 1.3 m, rather than at the base.

## 6.2.12 Data interpretation

The rate of increase in seedling biomass indicates the rate of regeneration of a site. To calculate this, measure the relative volume (as opposed to biomass) of seedlings per square metre within the transect, and its rate of increase over time. Slow or no increase in relative seedling volume and/or high seedling mortality rates may indicate environmental stress.

The relative volume of each seedling within a plot can be calculated from:

$$\text{Relative volume of seedling (cm}^3\text{)} = \frac{1}{3} \times \frac{1}{4} \times \pi D^2 \times H \text{ or } \frac{1}{3} \times \pi r^2 \times H$$

where:

$\pi = 3.14$  (approx.)

$D$  = Diameter of trunk (cm)

$H$  = Height of plant (cm)

$r$  = radius  $D/2$  (cm)

Seedlings differ widely in shape due to their leaves and branches, making true volume difficult to measure. Based on the two key indicators of plant size (stem diameter and height), and the 1/3 multiplication factor, this formula actually measures the volume of the plant stem as if it were pyramid-shaped. This is a relative measurement, allowing the growth rate of seedlings to be monitored and compared with other seedlings.

The total volume of seedlings in the transect is calculated by summing the volumes of all the seedlings measured. Divide the total volume by the area of the transect to give volume ( $\text{cm}^3/\text{m}^2$ ).

$$\text{Seedling volume cm}^3/\text{m}^2 = \frac{\Sigma \text{ relative seedling volume (cm}^3\text{)}}{\text{transect area (m}^2\text{)}}$$

where:  $\Sigma$  = Sum of individual seedling volumes

## 6.3 Canopy cover and leaf area index

### 6.3.1 Introduction—what is leaf area index and how is it related to mangrove forest health?

Leaf area index (LAI) is an index score of the total area of leaf surface within a plant community relative to the ground area of that community. Since plants under stress tend to shed leaves, thus reducing their leaf area, environmental stress can be detected by monitoring LAI. Significant decrease or gradual reduction over time in canopy cover and/or leaf area index score may indicate ecosystem stress or disturbance.

The LAI is not a true measurement of leaf area, but a relative score that can be used to compare results between sites and over time.

LAI can be used to monitor short to long-term foliage patterns and changes in a mangrove stand (e.g. high rates of primary productivity during good seasons, or defoliation through storm damage, seasonal or drought-related leaf fall, insect attack, etc.).

To calculate LAI, the intensity of full sunlight is measured (using a light meter), and this is compared with the light intensity measured under a mangrove canopy. Either a Lux or photosynthetic active radiation (PAR) meter is suitable. The cheap and robust Lux meters measure total light intensity, while the more expensive PAR meters measure photosynthetic active radiation, which is the light absorbed by plants during photosynthesis.

The choice of meter depends on the accuracy required. A scientific approach requires the more expensive and fragile PAR meter, which is highly sensitive and able to detect much smaller foliage pattern changes than the Lux meter can. However, despite some limitations, Lux meters can be used to detect and measure short-term changes to mangrove canopy cover.

Lux and PAR readings are not easily comparable, so choice of meter is important.

### 6.3.2 Method summary

Light readings are taken in the sun, outside the canopy of a homogenous mangrove community. A series of readings are then taken under the canopy, followed by a further series, again in the sun. LAI is determined by calculating the ratio of light under the canopy, to the light in the adjacent open space.

Best timing is midday  $\pm 2$  hours to ensure that the sun is as close to overhead as possible, and valid measurements can only be made on sunny days.

LAI measurement is not suitable for fringe mangrove environments, as light penetration from the edges will bias the result (e.g. on narrow river fringes).

### 6.3.3 Site selection

This method involves monitoring the LAI in wide, homogenous stands of mangroves. Prior to site selection, examine aerial photographs and look for patterns of zonation.

Select potential monitoring sites where mangrove forests are homogenous and are wide enough to minimise light infiltration from the forest edges.

At the site, walk through the forest and closely observe its structure (i.e. canopy height, species composition, and stem density) then select an area that appears to be representative of the mangrove community to be monitored. To avoid light penetration, ensure that there are at least 20 m between the quadrat and a forest edge.

Using the 50 m tape, mark out a quadrat of approximately 25 m x 25 m.

### 6.3.4 Using the light meter

Hold the light meter in one hand and the sensor in the other (see Figure 6.6), ensuring that the white surface of the sensor is facing upwards.

Turn on the light meter and select a range that is appropriate for the current light conditions.

To take a reading, blink your eyes and record the first reading that you see when you open them. A second person should carry the datasheets and record the results.

The light meter may have different range settings (e.g. x1, x10 and x100) to allow for a range of light intensities. When recording results, always record the range settings, or make the necessary corrections while taking measurements.

Wipe down the meter with a moist cloth after each use, treating the sensor with extreme care.

Always read instruction manuals for light meters, as some require the application of a correction factor.

Figure 6.6 Using a light meter

#### 6.3.4.1 Take the light meter readings

Take light readings outside the canopy:

- Turn on the light meter and set the range to 100x. Take five readings outside the canopy (multiplying each by 100 to adjust for range) and record the results.

Take light readings within the quadrat:

- Set the light meter to lx or 10x. Walk along the boundaries of the quadrat taking a light reading every metre for 100 m. Record the results, remembering to adjust for the range.
- When a light meter is used under a forest canopy, readings will occasionally go off-scale. If this happens, switch to a higher range setting and record the measurement on the new scale. Return to the original scale and continue to take readings. It is important to complete each set of readings within 30 minutes.

Take a light reading outside the canopy:

- Set the light meter to 100x and return to the outside of the canopy. Take another five readings and record the results.

#### 6.3.4.2 Measure the zenith angle of the sun

An instrument called a clinometer is used to measure the zenith angle of the sun, which is its angle from the vertical (see Figure 6.7). The closer it is to midday, the smaller this angle will be. If a clinometer is not available, insert a 1-2 m pole into a flat area of sunlit ground, ensuring it is at 90°. Measure the height of the stick and the length of its shadow.

$$\text{Zenith angle} = \frac{\text{Tan}^{-1} (\text{Length of shadow})}{\text{Height of stick}}$$

Alternatively, the zenith angle for the site can be calculated from a nautical almanac or from a suitable computer program using the latitude, longitude (or GPS reading) and time of day.

Figure 6.7 Zenith angle of the sun

### 6.3.5 Data interpretation

Calculate canopy cover and LAI of a plot using the following formulas:

$$\text{Canopy cover} = \frac{1 - \text{Average of canopy readings} \times 100}{\text{Average of open space readings}}$$

$$\text{LAI} = \text{Ln} \left( \frac{I_b}{I_0} \right) / -k \times \cos \left( \frac{\infty \pi}{180} \right)$$

where:

$I_b$  = Mean value of light below the canopy

$I_0$  = Mean value of light above the canopy

$k$  = is an extinction coefficient that accounts for the angle and orientation of the foliage (A  $k$  value of 0.55 has been chosen as appropriate for mangrove stands).

$\infty$  = Zenith angle of the sun

Ln = natural log of number

$\pi$  = Pi or 3.14

Note: The  $k$  value quoted can be used in calculations for closed canopy forests of *Rhizophora*, *Bruguiera* and *Ceriops* spp. but, due to the different structural characteristics of their canopies, is not suitable for use in closed canopy forests of *Avicennia* spp., or in open forests. However, as no  $k$  value has, as yet, been calculated for *Avicennia* stands, the nominated value can be used to calculate LAI, but the data can be compared only with that from other *Avicennia* stands.

Forest LAI and canopy cover are the mean results from each plot. Data can be displayed on histograms as the LA1 score, or as canopy cover per plot or forest over time. Median, range and standard deviations of readings are also calculated.

It is important to distinguish between natural and human-induced changes when interpreting data. As leaf area in canopies will naturally vary slightly from season to season, with a peak during the summer months, LAI can also vary naturally between sites and between different communities.

Large reductions in LAI are normally the result of disturbance or stress. If they are detected at a site, compare results from a control or other site (containing the same species) to determine if this reduction is local or more widespread. Volunteers can also return to the site to observe the forest closely for evidence of damage (e.g. storm damage, insect attack or stress).

## 6.4 Mangrove forest structure

### 6.4.1 Introduction—what is mangrove forest structure and how is it related to mangrove forest health?

Mangrove structure refers to the composition of a mangrove community in terms of canopy height, stem density, age, tree diameter and species represented. It varies considerably between different forest types, and between the same forest types in different locations. It is influenced by many natural factors including climate, tidal inundation, soil pH and salinity, sediment particle size and amount of freshwater.

Mangrove structure is likely to be affected when any of these parameters is altered (positively or negatively) by human-induced impacts. Positive changes can result in greater forest vigour (increased diameter, canopy cover and stem density), while negative changes can stress the mangrove community, resulting in reduced canopy cover, stem density, tree mortality and, eventually, reduced basal area of trees and/or lower canopy height.

Higher proportions of dead versus live stems, and/or decline in the basal area of the trunks of mangroves in a stand may indicate stress or past disturbance. Many aspects of mangrove structure tend to respond more slowly than most other estuarine indicators, and it can take several years before changes can be detected.

If saltmarshes are present, record the species types and estimate their percentage cover within the quadrat. Inspect the leaves of each tree for any signs of discoloration, wilting or insect damage. If there is insect damage, estimate the amount in terms of percentage loss of leaf surface area for the entire tree. If there are introduced vines, record the species (or describe their features) and estimate their percentage cover.

Also note any evidence of unusual occurrences, such as deposition of rubbish, or other human-induced disturbances.

### 6.4.2 Method summary

This method is used to provide baseline data on the diversity and structure of a mangrove community at a particular site, and to monitor long-term changes and provide a quantitative measure of species composition, stem density, and basal area of trees. This information can be useful for interpreting other parameters, such as leaf trapping ability and LAI. Changes to basal area, stem density and canopy cover can be indicators of ecosystem health.

The method is similar to the mangrove line transects method (English, Wilkinson & Baker 1997), but with some simplifications. Despite these, it is still a difficult, time-consuming method, and should be attempted only to study long-term changes to mangrove forests.

A transect running at right angles from the sea to the land is established, with 10 m x 10 m quadrats in each forest zone along the transect. Within each quadrat, the canopy cover, species type, tree height, sapling/seedling number and stem diameter are recorded.

### 6.4.3 Site selection

Though site selection will depend on the objectives of the monitoring program, in most instances it will be necessary to select sites that are representative of the mangroves in the area. Use aerial photographs to determine the size and extent of the site, and look for zonation patterns between the seaward and landward margins. Sites should be ground-truthed to confirm zonation patterns, and to ensure they are representative.

As mangrove systems are extremely diverse and can vary considerably in structure and floristics over short distances, a person of suitable experience should assist with this process.

### 6.4.4 Lay out transect and set up quadrats

If the program involves monitoring each homogenous zone, establish a transect beginning at right angles to the seaward side of the mangrove forest, and running to the landward edge (see Figure 6.8). Use the compass to establish the bearing to follow. Identify the major forest types or zones along the transect. For each forest type, find an area to the left of the transect that is representative (in terms of floristics and structure) of that mangrove community. If two quadrats are to be established, ensure that they are at least 20 m apart.

If monitoring a homogenous forest type or a narrow mangrove fringe along a creek, transects can be established parallel to the shoreline. Quadrats can be placed where the forest is representative of the mangrove community, or at regular intervals.

To set up a quadrat, mark out a 10 m x 10 m area within the forest. Use the compass to ensure that the corners are at 90 degrees, and mark each with a PVC pole (see Figure 6.9). Ensure that there is a minimum of 25 trees in each quadrat by increasing or decreasing its size if necessary (e.g. to 5 m x 5 m in a dense forest).

Figure 6.8 How to establish a quadrat and record position of tree using x/y coordinates

Figure 6.9 How to establish a transect

### 6.4.5 Estimate canopy cover

Imagine that the quadrat has been divided into four smaller quadrats. Stand in the middle of each of these imaginary quadrats and estimate the amount of sky that is blocked by the canopy. This score is referred to as canopy cover. (The illustrations in Figure 6.10 can be used as a guide.)

Calculate the average of these four estimates and record the result.

Note: If a light meter or forest densitometer is available, use this in preference to making visual estimates. See Section 6.3.4 for instructions on measuring canopy cover using a light meter.

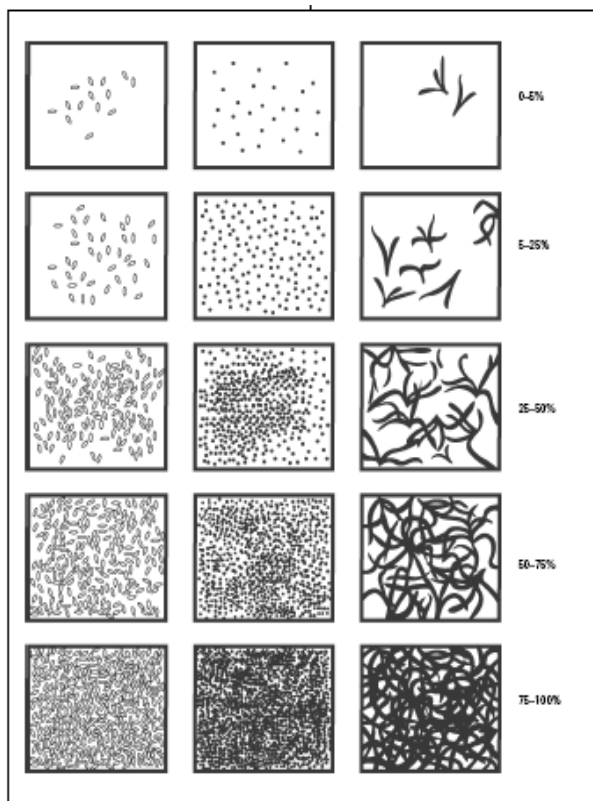

Figure 6.10 Estimating canopy cover

#### 6.4.6 Estimate canopy dominance

If the canopy consists of more than one species of mangrove, estimate the percentage that each species contributes to the total canopy cover.

Note: Dominance is not the same as canopy cover; the total of all species must equal 100 per cent. For example, if there is a 70 per cent canopy cover and only one species, canopy dominance by that species will be 100 per cent.

#### 6.4.7 Measure stem diameter

Measure the stem diameter of each tree at breast height (1.3 m above the ground) (see Figure 6.11). Measure only those trees with a stem diameter of 2.5 cm or more; do not measure saplings or seedlings (see Table 6.2).

Table 6.2 Criteria for distinguishing growth status

Tree	Stem DBH (1.3 m) 2.5 cm or greater
Sapling	Plant 1 m or more in height, with DBH < 2.5 cm
Seedling	Plant < 1 m in height

A diameter tape measures both circumference (girth) and the calculated diameter. Record result as diameter at breast height (DBH) (see Figure 6.11).

A tape measure measures circumference only. Record this as circumference at breast height, and calculate DBH by dividing this result by  $\pi$  (3.14 approx).

If carrying out long-term monitoring, hammer a galvanised nail (half of its length) into stems 10 cm below where measurements have been taken, to provide a reference point for future measurements. Note this on the datasheet.

Figure 6.11 Measurements recorded at breast of height

#### 6.4.7.1 How to measure irregularly shaped trees

Irregularly shaped trees are very common in mangrove forests. If an irregularity occurs at breast height (see Figure 6.12), use the following procedures to measure diameter:

- For multiple stems, fork below breast height; where stem diameter is 2.5 cm or greater, measure the diameter of each stem at breast height, and record all results in the same box on the datasheet. Do not count each stem as a separate tree.
- For multiple stems, fork at breast height; take the measurement slightly below the swelling caused by the fork. For buttress roots, take the measurement 30 cm above the uppermost prop root or buttress.
- For trunk swellings, take the measurement slightly above or below the swelling.

Some smaller mangrove forests may be naturally stunted or dwarf-like. In such situations these criteria are not suitable for determining growth status.

#### 6.4.8 Count saplings and seedlings

Count the number and record species type of seedlings and saplings within the quadrat. If plants are dense, use a smaller quadrat (size will depend on numbers, but 1 m x 1 m is a starting point), ensuring that the area sampled is representative of the larger quadrat. Estimate the number of seedlings/saplings within the 10 m x 10 m quadrat, based on the results of the smaller quadrat sampling

Figure 6.12 Measuring the stem diameter of irregularly shaped tree

### 6.4.9 Estimate height

To measure the height of each tree, stand the height pole up directly below the highest point of the tree (see Figure 6.13). Estimate the height of the tree to the nearest metre, based on the known length of the pole. Record the result.

Note: As this can be very difficult if the forest canopy is higher than 10 m, use of a clinometer is recommended in such situations.

### 6.4.10 Soils

Collect a sample of the substrate from the quadrat and rub it between your fingers. Record the sediment type based on its feel (e.g. sand, mud, sand/mud, mud/sand). Other information such as pH and salinity can be recorded also.

### 6.4.11 Tag and record position of trees

Since branches can die during long-term monitoring of a plot, attach alloy or stainless steel tags to the larger branches or to the main stem. Use nylon cable or stainless steel wire, ensuring that there is enough slack to allow for growth of the trees.

The position of trees should also be recorded using x/y coordinates (see Figure 6.8).

Figure 6.13 Using a height pole

#### 6.4.12 Measurements needed during re-survey

As it is likely that a long time may have elapsed before repeat measurements are made, the original corner marker may have disappeared, but plot boundaries can be located using the tags and the x/y coordinates. If new trees have become established, they should be assigned a new number.

#### 6.4.13 Data interpretation

Formal measurements provide quantitative data on the structure or level of ecological development of a mangrove community. Data is expressed as:

- stems (living and dead) per hectare
- basal area (square metres per hectare)
- tree height.

Stems per hectare (stems ha<sup>-1</sup>) is a measure of the density of living mangrove trees. It is calculated using the formula:

$$\text{Stems ha}^{-1} = \frac{\text{Number of living stems in plot} \times 10\,000}{\text{Area of the plot (m}^2\text{)}}$$

Stems ha<sup>-1</sup> should be calculated for each plot, together with the average for all the plots. The number of dead stems per hectare can also be calculated using the above formula, together with the overall ratio of dead to live stems (total dead stems versus total live stems).

Basal area (BA) of a plant refers to the cross-sectional area of its stem at 1.3 m (breast height). The basal area of a stand (stand BA) is the sum of all stem BAs in the quadrat, and is expressed as square metres per hectare (m<sup>2</sup>/ha). BA is a measure of the size or level of ecological development of a mangrove community. Normally, the higher the BA, the greater the biomass and level of development of a mangrove community.

Basal area for an individual plant is calculated using the following formula:

$$BA \text{ (cm}^2\text{)} = \pi r^2$$

where:

$$r = \text{radius of the stem (cm)} = \frac{\text{DBH (cm)}}{2}$$

$$\pi = 3.14 \text{ (approx)}$$

If the plant has multiple stems, the basal area for the plant will be equal to the sum of the basal areas of the individual stems.

To calculate stand BA, use the following formula:

$$\text{Stand BA (M}^2\text{/ha)} = \frac{\sum \text{BA for the plot (CM}^2\text{)}}{\text{Area of the plot (M}^2\text{)}}$$

where  $\Sigma$  BA = sum of individual BAs. Increases in BA over time may indicate that the community is still growing and developing. Increases in average canopy height will support this theory. A significant decrease in BA may indicate that disturbance has occurred—a theory that would be supported by an increase in the ratio of dead to live stems.

Average or median tree height can also be calculated to provide an indicator of canopy height. However, tree height measurements are better used to track the progress of individual trees, rather than that of the entire forest.

## **6.5 Crab burrow counts**

### **6.5.1 Introduction—why monitor crab hole density?**

Estuarine crabs break down much of the leaf and other organic matter produced by mangrove forests. Their burrows also increase the ratio of soil surface area to air, resulting in some aeration and oxidation of the mostly anoxic mangrove soils. This oxidation can be important for the growth of mangrove plants.

Consequently, changes to the crab population can affect the nutrient cycling and oxidation of intertidal soils, which in turn can affect the productivity of mangroves. Decreased crab populations and associated burrow density can lead to decreased nutrient cycling and soil aeration, and reduced production of surrounding plants.

Data on crab burrow density may complement leaf litter trapping or other mangrove monitoring exercises. Crabs can be sensitive to pollution. Their absence from a mangrove forest may indicate that the site is experiencing human-induced stress.

### **6.5.2 Method summary**

The number of crab burrows in a survey area is estimated by counting burrows within 50 cm x 50 cm quadrats. Monitor every three months.

### **6.5.3 Site selection**

This method is normally used in association with other methods, but if establishing a new site, ensure that it is in a homogenous mangrove forest, in an area representative of the surrounding forest.

### **6.5.4 Establish transects**

Establish three parallel 10 m transects through the site, 5 m apart. Mark the beginning and end of each with a peg to assist in locating the site again later.

### **6.5.5 Count the number of crab burrows**

Starting at 0 m, place a quadrat to the left of the transect and count the number of crab burrows within it. Burrows on the edge of the quadrat should be counted only if the centre of the hole is within the quadrat.

If crab holes are very numerous, use a 25 cm x 25 cm area of the quadrat and multiply the results by four.

Replace the quadrat and count crab holes every 2 m along the length of the transect.

### **6.5.6 Data interpretation**

Data is interpreted as crab holes per square metre (holes m<sup>-2</sup>).

Results may be highly variable between sites, so establish a baseline burrow density for each site. Long-term trends showing a significant decline in burrow numbers may indicate declining crab numbers and/or that the site is experiencing stress. Since crabs can have multiple burrow entrances and some species have been known to share burrows, the relationship is not linear.

Since crab hole abundance does not equate to absolute crab populations, significant changes in burrow counts would need to be recorded to indicate changes in population.

Crab holes can be covered by sediment plugs at low tide.

## Part G Monitoring seagrass

### 7.1 Intertidal percentage cover

#### 7.1.1 Introduction

Measurement of percentage cover can provide an early warning of seagrass decline and can be used to monitor the long-term health of seagrasses in a local area.

Significant reduction in percentage cover, or failure to recover after a disturbance, may indicate pressure on a seagrass meadow. Although the rate at which seagrass beds recover from disturbances such as floods is unknown, slow or no recovery may indicate other pressures.

#### 7.1.2 What is seagrass percentage cover?

Percentage cover is the percentage of a given area covered by seagrass (i.e. percentage cover is 100 per cent if the entire area is covered).

Percentage cover indicates the status and stage of development of a seagrass meadow. For example, if percentage cover is high and varies little over time, this indicates a stable, well-developed community. On the other hand, a reduction in cover, or increasing incidence of algae or epiphytes, may indicate natural or human-induced stress. Changes in percentage cover over time are also a useful indicator of the rate of recovery after disturbance.

### 7.2 Method for measuring seagrass percentage cover

#### 7.2.1 Method summary

Quadrats (50 cm x 50 cm) are placed at regular intervals along three transects in an intertidal seagrass community. See Figure 7.1 for guidance in the use of transects and quadrats.

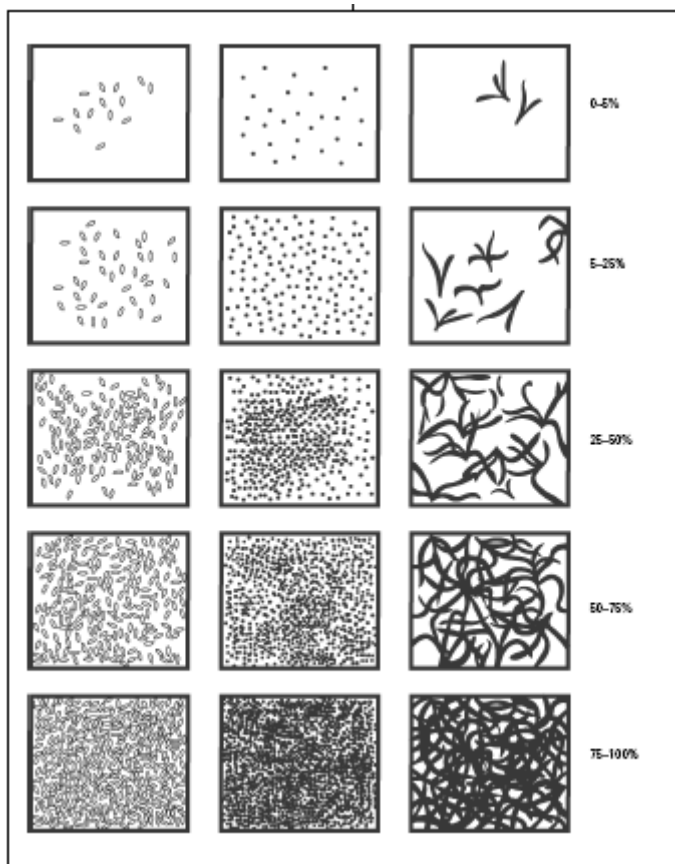

Figure 7.1 Using a transect

Percentage cover of seagrass in each quadrat can be rapidly assessed using the percentage cover illustration sheet (see Figure 7.2).

**Figure 7.2 Estimating cover**

Rapid visual estimates can be subject to individual observer bias; however, working in pairs can help reduce this. Shoot length and species dominance are recorded, and the percentage cover of algae and epiphytes is estimated.

Frequency of measurement should be a minimum of every three months to account for seasonal trends.

Water temperature, salinity and turbidity are also useful parameters to monitor along with seagrass parameters.

## 7.2.2 Site selection

Walk through a seagrass community to ensure that it is relatively homogenous and evenly shaped, with no sandbanks, mud ridges, or changes in the meadow. Select a 50 m x 50 m site that is representative of seagrass in the area concerned, has low variability, and is not difficult to revisit for future monitoring.

Once a site is selected, record its position using GPS and compass bearings from prominent land features to help relocate it again later.

### 7.2.2.1 Establishing transects

At least three transects are required at each site (see Figure 7.3). The middle transect at each site need to be permanently marked out. To mark where the middle transect begins, drive a plastic star picket into the ground at the landward edge until the top is only 10 cm above the surface, and attach the subsurface buoy. Record the position of the picket using a GPS.

Take a compass bearing from the site to the sea to ensure that the transect is at right angles to the shore. Holding the 50 m tape, follow the compass bearing ( $90^\circ$ ) for 50 m, and then take a back bearing ( $270^\circ$ ) to check your position and adjust if necessary. To mark the other end of the transect, drive a picket into the ground at this point.

Run transects 1 and 3 directly parallel to, and to the left and right of, transect 2. To do so, take a bearing at right angles to transect 2 and walk 25 m in that direction. Take a back bearing to check position and adjust if necessary. Set up transects 1 and 3 in the same way as transect 2.

When setting up the transect, hold the tape with the right hand. Always place the quadrats to the right of the transect, and walk on the left to avoid trampling the survey area. Photographic records of sample quadrats can be kept to complement the monitoring program and to assist with quality assurance. Stand above the quadrat (do not face the sun); place a quadrat photo labeller above the quadrats at 5 m, 25 m and 45 m, showing the site, transect and quadrat numbers; and take a photo. All monitoring should be conducted at low tide. Try to arrive about one hour before this to set up.

Figure 7.3 Overview of transect layer

#### 7.2.2.2 Estimate percentage cover and species composition

Place the 50 cm x 50 cm quadrat to the right of the transect at 0 m.

Estimate the percentage cover of seagrass in the quadrat using the illustrations in Appendix H as a guide. Record the result. Record the species of seagrasses in the quadrat, and determine the dominance of each (i.e. the percentage of cover that each species represents). These figures must total 100 per cent in all quadrats where seagrass is present.

#### **7.2.2.3 Measure blade length**

Ignoring the tallest 20 per cent of leaves, randomly select 3–5 seagrass blades from within the quadrat and measure their length (in cm) from the base to the end. Calculate the average and record the result.

#### **7.2.2.4 Sediment grain size composition**

Collect a sample of the substrate from the quadrat and rub it between your fingers. Based on its feel, estimate the grain composition. Record the result in order of dominance (e.g. sand, mud, sand/mud, mud/sand).

#### **7.2.2.5 Estimate epiphyte cover**

Measure the percentage cover of epiphytes (microalgae) on the seagrass blades within the quadrat. This figure should be the percentage of seagrass leaf area covered by epiphytes, not quadrat area.

#### **7.2.2.6 Estimate algal cover**

Estimate the percentage cover of both filamentous and macroalgal cover in the quadrat, using the procedure in step 7.2.2.2.

#### **7.2.2.7 Other information**

Record the presence of fauna species (including yabbie or worm holes) and any other features of interest, such as dugong trails.

#### **7.2.2.8 Repeat procedure**

Repeat steps 2–6 at 5 m intervals along the transect up to, and including, the 50 m mark (i.e. in 11 quadrats). Repeat procedure for each transect.

### **7.3 Data interpretation**

Data is presented as:

- mean percentage cover (per site, not per transect)
- mean algal cover
- mean epiphyte cover of seagrass blades
- mean shoot length.

Calculate the range and standard deviation of each parameter. Data is best presented as graphs or histograms which can be used to show trends over time at, and between, sites.

Bias in estimating percentage cover is a potential problem, particularly when values are low. If photographs of the quadrats have been taken, someone with experience can re-evaluate the estimates and a correction factor can be applied. Mean percentage values can be corrected if the level of error is known.

It is important to understand the natural changes that affect seagrass meadows. Seasonally, percentage cover is likely to be higher during the warmer months and lower during winter. To identify these trends it is necessary to collect data for a minimum of two years (but preferably more).

Significant gains or declines in percentage cover of seagrass at a site indicate that the seagrass bed is undergoing change. The rate of change should be compared with that at nearby sites (preferably ones with similar percentage cover) to determine if it is local or more widespread. A decline in cover may be due to environmental stress, while a gain can indicate recovery of a meadow after a flood event.

When comparing data between sites, it is important to realise that different levels of cover don't always indicate that one site is degraded. Some seagrass meadows may naturally have low cover.

High epiphyte and algal cover may indicate that nutrient enrichment is occurring at the site, particularly if there is freshwater or a local source of nutrient nearby. Values for these parameters are likely to be higher during the summer months.

A combination of blade length and percentage cover can indicate the structure of a seagrass meadow. For example, though a quadrat with very few shoots, but long leaf blades, may have the same percentage cover as one with many more shoots but much shorter blades, the structure of the meadow is very different in each.

## Part H Appendixes

### APPENDIX H1 Checklist of equipment needed for macroinvertebrate field sampling

	Tick when collected
<b>Macroinvertebrate sampling equipment</b>	
250µm macroinvertebrate sampling net	
Buckets x 4	
Sorting tray x 4	
Coarse sieve (10 mm)	
Tweezers and pipettes x 4	
Vials, vial labels and plastic bags	
Waders	
70% methylated spirits	
Squirt bottles	
<b>Water quality equipment</b>	
Alkalinity kit (check contents)	
Conductivity meter (ensure charged and calibrated)	
Dissolved oxygen meter (ensure charged and calibrated)	
pH meter (ensure charged and calibrated)	
Turbidity meter (ensure charged and calibrated)	
Water sample bottles (1 L and 250 mL)	
<b>General equipment</b>	
Site, habitat, water quality and macroinvertebrate field sheets	
Tape measure	
Waterplant and macroinvertebrate field identification books	
Current meter, staff and prop	
GPS	
Maps	
Sunscreen	
Car fridge or esky	
Drinking water	
Card table and chairs, beach umbrella or tarp and poles	
Camera and film	
Pens, pencils, erasers and clipboards	
Phone/radio	
First aid kit	
Shovel, 4WD recovery kit	

## APPENDIX H2 Queensland Site Information Sheet

This sheet can be completed at any stage of the program. Some information may be required prior to the trip. Some is collected during the trip and the rest is done afterwards when the site has been confirmed. This sheet only needs to be completed on the first visit to a site. Note: 1:100 000 topographic maps are used for the following information, where they are available. In some areas of Queensland, only 1:250 000 topographic maps are available.

**Latitude and longitude**—Use GPS (global positioning system) and confirm readings on a 1:100 000 topographic map.

**Altitude**—Use 1:100 000 topographic maps.

**Stream order**—Hierarchical ordering system based upon the degree of branching (Strahler 1957). Stream orders should be determined using 1:100 000 scale maps. A second-order stream is formed by the joining of two first order-streams; the junction of two second-order streams forms a third order stream, etc. (see Figure H1).

Figure H1 Method used by DERM to determine stream order (Strahler 1957)

**Slope (m/m).** =  $\frac{\text{contour distance (m)}}{\text{distance of stream between contour lines (m)}}$

e.g. 6.5 km between 20 m and 40 m contour lines =  $20\text{m}/6500\text{m} = 0.0031\text{m/m}$

**Distance from source (km)**—Distance from the site to longest thread of stream source.

**AMTD (km)** (adjusted middle thread distance)—The distance from the mouth of the stream (i.e. at the ocean or where it joins another stream) to the site.

**Reach**—An assessment of where in the catchment a site lies with relation to the watershed. Note that this does not necessarily correlate to the altitude.

**Catchment area (km<sup>2</sup>)**—The area of land above the site being assessed from which the water drains towards the stream.

**Reference or test assessment**—Determined using the Reference Condition Selection Criteria (Table 1 and page 3 of Site Information Sheet).

**Nearest rainfall station**—Within DERM, a departmental database called DRF is used. The same information can be extracted from the Bureau of Meteorology website <[www.bom.gov.au](http://www.bom.gov.au)>. Recording the station name eliminates searches for the closest station when there is a need to verify/update data.

**Nearest weather station**—Temperature information can be extracted from the Bureau of Meteorology website (see above). Again, recording the station name eliminates searches for the closest station when there is a need to verify/update data.

**Mud map of access route**

**Sketch of reach**

No.	Reference condition selection criteria	Level of impact *
1	Influence of intensive agriculture upstream*  Intensive agriculture is that which involves irrigation, widespread soil disturbance, use of agrochemicals and pine plantations. Dry-land grazing does not fall into this category.	
2	Influence of major extractive industry (current or historical) upstream*  This includes mines, quarries and sand/gravel extraction.	
3	Influence of major urban area upstream  This will be relative to population size, river size and distance between the site and the impact.	
4	Influence of significant point-source waste water discharge upstream*  Exceptions can be made for small discharges into large rivers.	
5	Influence of dam or major weir*  Sites within the ponded area of impoundments also fail. Sites failing this criterion automatically fail the overall assessment.	
6	Influence of alteration to seasonal flow regime  This may be due to abstraction or regulation further upstream than the coverage by Criterion 5. Includes either an increase or decrease in seasonal flow.	
7	Influence of alteration to riparian zone  Riparian vegetation should be intact and dominated by native species.	
8	Influence of erosion and damage by stock on riparian zone and banks  Stock damage to the stream bed may be included in this category.	
9	Influence of major geomorphological change on stream channel  Geomorphological change includes bank slumping, shallowing, braiding and unnatural aggradation or degradation.	
10	Influence of alteration to instream conditions and habitats  This may be due to excessive algal and macrophyte growth, by sedimentation and siltation, by reduction in habitat diversity by drowning or drying out of habitats (e.g. riffles) or by direct access of stock into the river.	
	<b>SITE ASSESSMENT</b>	/50

\* Note: the level of impact at a site will generally decrease as the distance from the source of impact increases.

Each criterion relates to an aspect of human activity that impacts on freshwater ecosystems, where impact is defined as a 'change from natural condition'. Each criterion is given a score according to the following categories:

1. Very major impact
2. Major impact
3. Moderate impact
4. Minor impact
5. Indiscernible impact.

Sites are assessed using the total score for the 10 criteria. Those sites that have a total greater than 44 are deemed to be reference sites. Sites that are given a score of 1, 2 or 3 for criterion 5 (no dam or major weir upstream) cannot be reference sites.

## **APPENDIX H3 Water Quality Sampling Field Sheet**

This field sheet is intended to record information about the water quality parameters (DO, conductivity, water temperature, etc.) and factors that may have an influence on the water quality parameters (e.g. adjacent land use, bank erosion, etc.). The information on the sheet refers to the entire site (100 m reach) at the time it is sampled.

The front side of this sheet is a generic departmental water quality sheet which enables DERM officers to record information on the water quality sample collection site and field measurements, as well as noting the relevant samples and paperwork for external laboratory analysis. The reverse side of this sheet records observations of factors that may influence the water quality from the entire reach. Information on the types of macrophytes present can also be recorded as well as any notes

## **APPENDIX H4 Macroinvertebrate Sampling Field Sheet**

This sheet contains information about the macroinvertebrate habitats sampled (water depth and velocity, substrate description, etc.) with longitudinal and cross-sectional sketches of the 100 m reach.

Most of the values derived for this field sheet are estimated, apart from the water velocity, mean depth and the mean channel width. The mean channel width is the distance between left bank water's edge and right bank water's edge.

The sketches are important for helping to assess the sites after they have been visited. These should include where the water and macroinvertebrate samples were taken, where any photos were taken, the approximate bank height (measured from the water level to the top of the bank), bank width, stream width and depth, where each of the different aquatic habitats are, and the width and composition of the riparian vegetation

# APPENDIX H5 Habitat Assessment Field Sheet

## River Bioassessment Program

### HABITAT ASSESSMENT FIELD SHEET

SITE NUMBER: [ | | | | ] SITE NAME: \_\_\_\_\_

Date: / / Time (24 hrs): [ | | ] GPS: \_\_\_\_\_ Project Name: \_\_\_\_\_

Habitat Variable	CATEGORY		
	Excellent	Good	Fair
1. Bottom substrate/available cover	Greater than 50% rubble, gravel, submerged logs, undercut banks or other stable habitat.  20, 19, 18, 17, 16	30-50% rubble, gravel or other stable habitat. Adequate habitat.  15, 14, 13, 12, 11	10-30% rubble, gravel or other stable habitat. Habitat availability less than desirable.  10, 9, 8, 7, 6
2. Embeddedness	Gravel, cobble and boulder particles are between 0 & 25% surrounded by fine sediment.  20, 19, 18, 17, 16	Gravel, cobble and boulder particles are between 25% & 50% surrounded by fine sediment.  15, 14, 13, 12, 11	Gravel, cobble and boulder particles are over 75% surrounded by fine sediment.  5, 4, 3, 2, 1, 0
3. Velocity/depth category	Slow deep (<0.3 m/s & >0.5 m); slow shallow; fast deep; fast shallow; habitats all present.  20, 19, 18, 17, 16	Only 3 of the four habitat categories present (missing riffles or runs receive lower score than missing pools).  15, 14, 13, 12, 11	Only two of the four habitat categories present (missing riffles/runs receive lower score).  10, 9, 8, 7, 6
4. Channel alteration	Little or no enlargement of islands or point bars and/or no channelisation.  15, 14, 13, 12	Some new increase in bar formation, mostly from coarse gravel, and/or some channelisation present.  11, 10, 9, 8	Moderate deposition of new gravel, coarse sand, on old and new bars; pools partly filled with silt; and/or embankments on both banks.  7, 6, 5, 4
5. Bottom scouring and deposition	Less than 5% of the bottom affected by scouring and deposition.  15, 14, 13, 12	5-30% affected. Scours at constrictions and where grades steepen, some deposition in pools.  11, 10, 9, 8	More than 50% of the bottom changing nearly year long. Pools almost absent due to deposition. Only large rocks in riffle exposed.  3, 2, 1, 0

River Bioassessment Program

**HABITAT ASSESSMENT FIELD SHEET cont.**

Habitat Variable	CATEGORY		
	Excellent	Good	Fair
6. Pool/riffle, run/bend ratio. (Distance between riffles divided by stream width)	0-7 Variety of habitat. Deep riffles and pools.  15, 14, 13, 12	7-15 Adequate depth in pools and riffles. Bends provide habitat.  11, 10, 9, 8	15-25 Occasional riffle or bend. Bottom contours provide some habitat.  7, 6, 5, 4
7. Bank stability	Stable. No evidence of erosion or bank failure. Side slopes generally <30%. Little potential for future problem.  10, 9	Moderately stable. Infrequent, small areas of erosion mostly healed over. Side slopes up to 40% on one bank. Slight potential in extreme floods.  8, 7, 6	Moderately unstable. Moderate frequency and size of erosional areas. Side slopes up to 60% on some banks. High erosion potential during extreme/high flows.  5, 4, 3
8. Bank vegetative stability	Over 80% of the streambank surfaces covered by vegetation or boulders and cobble.  10, 9	50-79% of the streambank surfaces covered by vegetation, gravel or larger material.  8, 7, 6	25-49% of the streambank covered by vegetation, gravel or larger material.  5, 4, 3
9. Streamside cover	Dominant vegetation is of tree form.  10, 9	Dominant vegetation shrub.  8, 7, 6	Dominant vegetation is grass, sedge, ferns.  5, 4, 3
			Poor >25 Essentially a straight stream. Generally all flat water or shallow riffle. Poor habitat.  3, 2, 1, 0
			Unstable. Many eroded areas. Side slopes > 60% common. 'Raw' areas frequent along straight sections and bends.  2, 1, 0
			Less than 25% of the streambank surfaces covered by vegetation, gravel or larger material.  2, 1, 0
			Over 50% of the streambank has no vegetation and dominant material is soil, rock, bridge materials, culverts, or mine tailings.  2, 1, 0

#### FIELD SAMPLING TASKS TO BE COMPLETED

\* Please check off each item before leaving a sampling site. \*

SITE NO..... SITE NAME.....

**Plan sketch of 100 m stream reach to be sampled; to include:**

- location of different habitats, macrophytes and other vegetation
- location of biological sampling sites
- location of water quality measurement sites
- location of water collection sites for GCL samples
- location of x-sectional profile sketch
- location from where photograph(s) taken
- scale

**X-sectional profile sketch; to include:**

- stream width
- bank heights
- riparian vegetation heights

**Photograph(s)/video of sampling site**

**Biological sampling of the different habitats and 60 min. random picking for each**

**Biological samples preserved in 80% methylated spirits, labelled and stored upright**

**Water quality measurements taken**

**Water quality samples for GCL collected, labelled and stored appropriately**

**Field sheets 1, 2 and GCL water analysis input sheets completed, checked and initialled**

**Gauge height/flow recorded**

**GPS recorded**

## APPENDIX H8 Keys used for identification of Queensland Macroinvertebrate Fauna

### Keys used for identification of Queensland macroinvertebrate fauna

Order	Author/editor	Year	Key
General keys	Hawking, J.H.	1999	A preliminary guide to keys and zoological information to identify invertebrates from Australian freshwaters
General keys	Merritt, R.W. & Cummins, K.W.	1996	An introduction to the aquatic insects of North America (third edition)
General keys	Hawking, J.H.	1995	Monitoring River Health Initiative taxonomic workshop handbook
General keys	CSIRO	1991	The insects of Australia (second edition) Volume 1
General keys	CSIRO	1991	The insects of Australia (second edition) Volume 2
General keys	CSIRO	1999	Interactive guide to Australian aquatic invertebrates, Edition 2 (CD ROM)
General keys	Williams, W.D.	1980	Australian freshwater life
Acarina	Harvey, M.S. & Grown, J.E.	1998	A guide to the identification of families of Australian water mites (Arachnida: Acarina)
Coleoptera	Glaister, A.	1999	Guide to the identification of Australian Elmidae larvae (Insecta: Coleoptera)
Coleoptera	Watts, C.	1998	Preliminary guide to the identification of adult and larval Dytiscidae and adult aquatic Hydrophilidae
Coleoptera	Davis, J.	1998	(Insecta: Coleoptera) A guide to the identification of larval Psephenidae water pennies (Insecta: Coleoptera)
Crustacea	Sheil, R.	2000	Cladocera (Crustacea)
Crustacea	Wilson, G.D.F.	1999	Phreatoicidae (Isopoda, Crustacea)
Crustacea	Bradbury, J.	1999	Described Australian Amphipoda
Crustacea	Griggs, J.A., Shiel, R.J. & Croome, R.L.	1999	A guide to the identification of Chydorids (Branchiopoda: Anomopoda) from Australian inland waters
Crustacea	Horwitz, P., Knott, B. & Williams, W.D.	1995	A preliminary key to the Malacostracan families (Crustacea) found in Australian inland waters
Crustacea	Horwitz, P.	1995	A preliminary key to the species of Decapoda (Crustacea: Malacostraca) found in Australian inland waters
Crustacea	Shiel, R.J.	1995	A guide to identification of rotifers, Cladocerans and Copepods from Australian inland waters
Crustacea	De Deckker, P.	1995	Notes to help identify Ostracods from Australian inland waters and a guide to Ostracod dissection; Attempt at keying Australian Ostracods for their identification
Diptera	Cranston, P.	1997	Identification guide to the Chironomidae of New South Wales
Diptera		1995	Key to aquatic diptera families
Ephemeroptera	Suter, P.J.	1999	Illustrated key to the Australian Caenid nymphs (Ephemeroptera: Caenidae)

Ephemeroptera	Suter, P.J.	1997	Preliminary guide to the identification of nymphs of Australian Baetid mayflies (Insecta: Ephemeroptera) found in flowing waters
Ephemeroptera	Dean, J.C. & Suter, P.J.	1996	Mayfly nymphs of Australia—a guide to genera
Hemiptera	Moller Andersen, N. & Weir, T.A.	1994	Austrobates rivularis, gen. Et sp. Nov., a freshwater relative of Halobates Eschscholtz (Hemiptera: Gerridae), with a new perspective on the evolution of sea skaters
Hemiptera	Moller Andersen, N. & Weir, T.A.	1994	The Girrine water striders of Australia (Hemiptera: Gerridae): Taxonomy, distribution and ecology
Hemiptera	Moller Andersen, N. & Weir, T.A.	1994	The sea skaters, genus Halobates Eschscholtz (Hemiptera: Gerridae), of Australia: Taxonomy, Phylogeny and Zoogeography
Megaloptera	Theischinger, G.	2000	Australian alderfly larvae and adults (Insecta: Megaloptera) a preliminary guide to the identification of larvae and survey of adults of Australian alderflies.
Mollusca	Ponder, W.F., Clark, S.A. & Dallwitz, M.J.	2000	Freshwater and estuarine molluscs: An interactive, illustrated key for New South Wales
Mollusca	Miller, A.C., Ponder, W.F. & Clark, S.A.	1999	Freshwater snails of the genera Fluvidona and Austropyrgus (Gastropoda, Hydrobiidae) from northern New South Wales and southern Queensland, Australia.
Mollusca	Smith, B.J.	1996	New South Wales and southern Queensland, Australia: Identification keys to the families and genera of bivalve and gastropod molluscs found in Australian inland waters
Mollusca	Sheldon, F. & Walker, K.F.	1993	Shell variation in Australian Notopala (Gastropoda: Prosobranchia: Viviparidae)
Mollusca	Smith, B.J.	1992	Zoological catalogue of Australia—non-marine Mollusca
Mollusca	Walker, J.C.	1988	Classification of Australian buliniform planorbids (Mollusca: Plumonata)
Mollusca	Stoddart, J.A.	1985	Analysis of species lineages of some Australian thiarids (Thiaridae, Prosobranchia, Gastropoda) using the evolutionary species concept
Mollusca	Kuiper, J.G.J.	1983	The Sphaeriidae of Australia (extract only)
Mollusc		1966	Studies on Ancyliidae
Mollusca	Stoddart, J.A.		Western Australian Viviparids (Prosobranchia: Mollusca)
Mollusca	Brown, D.S.		Observations on Planorbinae from Australia and New Guinea
Odonata	Hawking, J. & Theischinger, G.	1999	Dragonfly larvae (Odonata)—a guide to the identification of larvae of Australian families and identification and ecology of larvae from New South Wales
Odonata	Theischinger, G.	2000	Preliminary keys for the identification of larvae of the Australian Gomphides (Odonata)
Plecoptera	Yule, C.	1997	Identification guide to the stonefly nymphs of New South Wales and northern Victoria

Plecoptera	Tsyrlin, E.	1999	Preliminary key to mature nymphs of Leptoperla stoneflies in Victoria
Trichoptera	St.Clair, R.M.	2000	Preliminary keys for the identification of Australian Caddisfly larvae of the family Leptoceridae
Trichoptera	St.Clair, R.M.	2000	Preliminary keys for the identification of Australian Caddisfly larvae of the families Odontoceridae, Kokiriidae and Oeconesidae
Trichoptera	Dean, J.C.	2000	Preliminary keys for the identification of Australian Caddisfly larvae of the families Antipodoeciidae, Atriplectididae, Limnephilidae and Plectrotarsidae
Trichoptera	Dean, J.C. & St Clair, R.M.	1999	Taxonomy of immatures of selected families of Ephemeroptera and Trichoptera
Trichoptera	Dean, J.C.	1999	Preliminary keys for the identification of Australian Trichoptera larvae of the family Hydropsychidae
Trichoptera	Cartwright, D.I.	1998	Preliminary guide to the identification of late instar larvae of Australian Polycentropodidae, Glossosomatidae, Dipsuedopsidae and Psychomyiidae (Insecta: Trichoptera)
Trichoptera	Jackson, J.	1998	Preliminary guide to the identification of late instar larvae of Australian Calocidae, Helicophidae and Conoesucidae
Trichoptera	St Clair, R.M.	1997	Conoesucidae (Insecta: Trichoptera) – Preliminary guide to the identification of late instar larvae of Australian Philorheithridae, Calamoceratidae and Helicopsychidae (Insecta: Trichoptera)
Trichoptera	Dean, J.C.	1997	A preliminary guide to the identification of larval Hydroptilidae (Insecta: Trichoptera)
Trichoptera	Wells, A.	1997	A key to species of late instar larvae of Australian Trichoptera (families Dipseudopsidae, Glossosomatidae, Polycentropodidae, Psychomyiidae, Ecnomidae, Philopotamidae and Tasmidae)
Trichoptera	Cartwright, D.I.	1997	Identification of late instar larvae of Australian Trichoptera genera
Trichoptera	Dean, J.C., St Clair, R.M., Cartwright, D.I. & Wells, A.	1996	Freshwater snails of the genera Fluvidona and Austropyrgus (Gastropoda, Hydrobiidae) from northern New South Wales and southern Queensland, Australia.

## Appendix H9 List of predictor variables used for the Mark I and Mark II models

### Predictor variables used for the Mark I and Mark II models

<b>Mark I</b>			
<b>Spring edge</b>	<b>Spring bed</b>	<b>Autumn edge</b>	<b>Autumn bed</b>
Depth (m)	Bedrock (%)	Alkalinity (mg/L)	Altitude (m) Cobble
Distance from source (km)	Cobble (%)	Distance from source (km)	(%) Gravel (%)
Latitude <sup>1</sup>	Gravel (%)	Latitude <sup>1</sup>	Maximum velocity (m/s)
Longitude <sup>1</sup>	Latitude <sup>1</sup>	Longitude <sup>1</sup>	Water body description <sup>2</sup>
Water body description <sup>2</sup>	Macrophyte cover <sup>3</sup>	Minimum velocity (m/s)	Sand (%) Silt (%)
Water temperature (°C)	Minimum velocity (m/s)	Stream slope (m/m)	Stream order
	Water body description <sup>2</sup>		Stream slope (m/m)
	Stream slope (m/m)		Stream wetted width (m)
			Water temperature (°C)
<b>Mark II</b>			
<b>Spring edge</b>	<b>Spring pool</b>	<b>Autumn edge</b>	<b>Autumn pool</b>
		Alkalinity (mg/L)	Alkalinity (mg/L) Bedrock
		Cobble (%)	(%) Cobble (%)
		Number of habitats	Distance from source (km)
		Latitude <sup>1</sup>	Latitude <sup>1</sup>
		Longitude <sup>1</sup>	Longitude <sup>1</sup>
		Mean annual rainfall (mm)	Mean dry season monthly rainfall (mm)
		Slope (m/m)	(MDMR)
		Soil class <sup>4</sup>	Pebble (%)
		Stream order	Ratio of mean wet to mean dry season monthly rainfall (mm)
		Water temperature (°C)	(RAWD)
		Range in wet season; monthly rainfall means (mm) (WETR)	Reach category <sup>5</sup>
			Stream wetted width (m)

<sup>1</sup> Decimal degrees.

<sup>2</sup> (reflow) 1: some part of water body flowing; 2: No flow—surface area <100 m<sup>2</sup>; 3: No flow—surface area >100 m<sup>2</sup>.

<sup>3</sup> Measured in the habitat: 0: none (0%); 1: little (1-30%); 2: moderate (31-70%); 3: extensive (>70%).

<sup>4</sup> Soil class number (1-11)—attained from GIS map overlay.

<sup>5</sup> 0: lower; 1: middle; 2: upper.

<sup>6</sup> Number of substrate categories in reach (bedrock, boulder, cobble, pebble, gravel, and silt/clay—7 categories in total).

## Appendix H11 Transport of live aquatic animals

### Unaccompanied road transport

Place finfish/crustacea in two strong large plastic bags, with the inner one 1/4 to 1/3 full of water from the pond or tank from which the animals came (Figure H2a). Fill the inner bag with air (for a 1-2 hour trip) or oxygen (for a longer trip). Be sure to expel all air from the inner bag prior to filling with oxygen. Bring the top together, fold back on itself and seal with a rubber band (Figure H2b). Seal the second plastic bag over the top of the inner one (Figure H2c).

Place the bag in a large insulated container, e.g. a polystyrene esky. Label correctly and include written information on the history/problem of the animals it contains (attach to outside).

### Accompanied road transport

The above method may be used. Alternatively, a plastic rubbish bin lined with a large unsealed plastic bag may be used. The transported water can be aerated during the trip with a portable battery-operated aquarium air pump or a fisherman's bait aerator.

### Air transport

Transport of live animals within a state by air must conform to current Australian Domestic Airline Seafood Regulations and Packaging Approvals and IATA regulations as specified by the airline. The regulations outline the correct packing procedures and the approved transport box to be used. For example, live freshwater fish must be packed and transported according to IATA regulations, while the transport of live saltwater fish must comply with the current Australian Domestic Airline Seafood Regulations and Packaging Approvals. Contact the freight section of your nearest airport to check requirements before packing and transporting live fish to the laboratory.

NOTE: Interstate transport of sick animals is illegal, since there may be a risk of introducing a disease to a state declared free of a particular disease. You must contact your nearest Animal Health Laboratory within Queensland if you have a suspected disease outbreak.

Figure 22. Packing method for transport of live fish

## Glossary of useful terms

Abiotic	The non-living components of a system (see biota).
Absorption	In chemistry: penetration of one substance into the body of another. In biology: the act of absorbing (i.e. to take in as fluids or gases through a cell membrane). To take a substance (e.g. water, nutrients) into the body through the skin or mucous membranes or, in plants, through root hairs. See also Adsorption.
Acidic	Having a high hydrogen ion concentration (low pH).
Acid-soluble metal	The concentration of a metal that passes through a 0.45 micron ( $\mu\text{m}$ ) membrane filter after the sample is acidified to pH 1.5–2.0 with nitric acid.
Acid volatile sulphide (AVS)	Sulfides in sediment that liberate hydrogen sulphide on reaction with cold dilute acid (mainly FeS or MnS in sediments).
Acute toxicity	Rapid adverse effect (e.g. death) caused by a substance in a living organism. Can be used to define either the exposure or the response to an exposure (effect).
Adsorption	The taking up of one substance at the surface of another.
Aerobic	Organisms requiring oxygen for respiration or conditions where oxygen is available.
Algae	Comparatively simple chlorophyll-bearing plants, most of which are aquatic and microscopic in size.
Alkalinity	The quantitative capacity of aqueous media to react with hydroxyl ions. The equivalent sum of the bases that are titratable with strong acid. Alkalinity is a capacity factor that represents the acid neutralising capacity of an aqueous system.
Ambient waters	All surrounding waters, generally of largely natural occurrence.
Anaerobic	Conditions where oxygen is lacking (anoxic); organisms not requiring oxygen for respiration.
Analyst	A particular person in the receiving laboratory who is to perform or supervise the analyses on the samples in question and has recognised qualifications.
Analytes	The physical and chemical species (indicators) to be determined.
Antagonism	A phenomenon in which the effect or toxicity of a mixture of chemicals is less than that which would be expected from a simple summation of the effects or toxicities of the individual chemicals present in the mixture.
Anthropogenic	Produced or caused by humans.
Aquatic ecosystem	Any watery environment from small to large, from pond to ocean, in which plants and animals interact with the chemical and physical features of the environment.
Aquifer	An underground layer of permeable rock, sand or gravel that absorbs water and allows it free passage through pore spaces.
Assimilation	The incorporation of absorbed substances into cellular material.
Assimilative capacity	The maximum loading rate of a particular pollutant that can be tolerated or processed by the receiving environment without causing significant degradation to the quality of the ecosystem and hence the environmental values it supports.
Baseline data	Also called pre-operational data (studies); collected (undertaken) before a development begins.

Benthic	Referring to organisms living in or on the sediments of aquatic habitats (lakes, rivers, ponds, etc.).
Benthos	The sum total of organisms living in, or on, the sediments of aquatic habitats.
Bioaccumulation	General term describing a process by which chemical substances are accumulated by aquatic organisms from water, either directly or through consumption of food containing the chemicals.
Bioassay	A test that exposes living organisms to several levels of a substance that is under investigation, and evaluates the organism's responses.
Bioavailable	The fraction of the total of a chemical in the surrounding environment that can be taken up by organisms. The environment may include water, sediment, soil, suspended particles, and food items.
Biochemical (or Biological) Oxygen Demand (BOD)	The decrease in oxygen content in mg/L of a sample of water in the dark at a certain temperature over a certain of period which is brought about by the bacterial breakdown of organic matter. Usually the decomposition has proceeded so far after 20 days that no further change occurs. The oxygen demand is measured after five days (BOD5), at which time 70% of the final value has usually been reached.
Bioconcentration factor (BCF)	A unitless value describing the multiple by which a chemical can be concentrated in the tissues of an organism in the aquatic environment. At apparent equilibrium during the uptake phase of a bioconcentration test, the BCF is the concentration of a chemical in one or more tissues of the aquatic organisms divided by the average exposure concentration in the test.
Biodiversity (biological diversity)	The variety of life forms, including the plants, animals and microorganisms, the genes they contain and the ecosystems and ecological processes of which they are a part.
Biofilm	Layer of materials created by microorganisms on an underwater surface.
Biological assessment	Use and measurement of the biota to monitor and assess the ecological health of an ecosystem.
Biological community	An assemblage of organisms characterised by a distinctive combination of species occupying a common environment and interacting with one another.
Biomagnification	Result of the processes of bioconcentration and bioaccumulation by which tissue concentrations of bioaccumulated chemicals increase as the chemical passes up through two or more trophic levels. The term implies an efficient transfer of chemicals from food to consumer, so that residue concentrations increase systematically from one trophic level to the next.
Biomass	The living weight of a plant or animal population, usually expressed on a unit area basis.
Biosolids	Sewage sludge, organic residuals remaining after domestic sewage treatment.
Biota	The sum total of the living organisms of any designated area.
Bioturbation	The physical disturbance of sediments by burrowing and other activities of organisms.
Bivalve	A mollusc with a hinged double shell.
Bloom	An unusually large number of organisms per unit of water, usually algae, made up of one or a few species.
Buffer	A solution containing a weak acid and its conjugate weak base, the pH of which changes only slightly on the addition of acid or alkali.

Buffering capacity	A measure of the relative sensitivity of a solution to pH changes on addition of acids or base.
°C	Degrees Celsius.
Carcinogen	A substance that induces cancer in a living organism.
Catchment	The total area draining into a river, reservoir, or other body of water.
Chemical oxygen demand (COD)	The amount of oxygen required to oxidise all organic matter that is susceptible to oxidation by a strong chemical oxidant.
Chlorination	<ul style="list-style-type: none"> <li>• The process of introducing one or more chlorine atoms into a compound.</li> <li>• The application of chlorine to water, sewage or industrial wastes for disinfection.</li> </ul>
Chronic	Lingering or continuing for a long time; often for periods from several weeks to years. Can be used to define either the exposure of an aquatic species or its response to an exposure (effect). Chronic exposure typically includes a biological response of relatively slow progress and long continuance, often affecting a life stage.
Chronic value	The geometric mean of the lower and upper limits obtained from an acceptable chronic test or by analysing chronic data using a regression analysis. A lower chronic limit is the highest tested concentration that did not cause an unacceptable amount of adverse effect on any of the specified biological measurements, and below which no tested concentration caused unacceptable effect. An upper chronic limit is the lowest tested concentration that did cause an unacceptable amount of adverse effect on one or more biological measurements and above which all tested concentrations also caused such an effect.
Colloid	Material in solution typically 1 nm–100 nm in diameter. Colloidal particles do not settle out of solution through the force of gravity. Organic colloidal matter is considered especially important in the transport of inorganic substances such as P through the soil profile.
Community	An assemblage of organisms characterised by a distinctive combination of species occupying a common environment and interacting with one another.
Community composition	All the types of taxa present in a community.
Community metabolism	The biological movement of carbon in an ecosystem, involving two processes, production (via photosynthesis) and respiration.
Community structure	All the types of taxa present in a community and their relative abundances.
Compliance	Action in accordance with upholding a 'standard' (water quality).
Concentration	The quantifiable amount of chemical in, say, water, food or sediment.
Criteria (water quality)	Scientific data evaluated to derive the recommended quality of water for different uses.
Cyanobacteria	A division of photosynthetic bacteria, formerly known as blue-green algae that can produce strong toxins.
Cytotoxic	Having an adverse impact on living cells.
Decision criteria	Criteria by which decisions will be made as a result of monitoring for potential impacts.

Depuration	Process whereby the re is elimination of contaminant from the tissues when an organism is surrounded by uncontaminated water or sediment; also used to describe the use of a controlled aquatic environment to reduce the level of pathogenic organisms that may be present in live shellfish prior to marketing.
Detection limit	The smallest concentration or amount of a substance that can be reported as present with a specified degree of certainty by definite complete analytical procedures.
Detritus	Unconsolidated sediments composed of both inorganic and dead and decaying organic material.
Dinoflagellates	Major class of marine algae that move by flagella. They are often red in colour, and can produce strong toxins that can kill many fish and other marine organisms.
Direct toxicity assessment (DTA)	A laboratory procedure for quantifying the potential toxicity of a sample of effluent through exposing a range of test specimens to that effluent. It assesses the toxicity of mixtures of bioavailable chemicals rather than individual chemicals. Also known as Whole Effluent Toxicity (WET) testing.
Diurnal	Daily.
Dose	The quantifiable amount of a material introduced into an animal.
EC50	(or median effective concentration) The concentration of material in water that is estimated to produce a measurable response in 50% of the test organisms. The EC50 is usually expressed as a time-dependent exposure value (e.g. 24-hour or 96-hour EC50). See also LC50.
Effect size	The size of impact that would cause concern (or constitute an early warning). Often defined as a level of (ecological) change that is acceptable in comparison to a defined reference.
Effluent	A complex waste material (e.g. liquid industrial discharge or sewage) discharged into the environment.
Electrical conductivity	The ability of water or soil solution to conduct an electric current.
End-points	Measured attainment response, typically applied to ecotoxicity or management goals.
Endemic, endemism	Confined in occurrence to a local region.
Enterococci	Any streptococcal bacteria normally found in the human intestinal tract; usually non-pathogenic.
Environmental authority or development approval	A licence, permit or other authority for an environmentally relevant activity, granted by an administering body in accordance with the <i>Environmental Protection Act 1994</i> .
Environmental values	Particular values or uses of the environment that are important for a healthy ecosystem or for public benefit, welfare, safety or health and that require protection from the effects of pollution, waste discharges and deposits. Several environmental values may be designated for a specific water body.
Ephemeral stream	A stream that carries water only during or immediately after periods of rainfall.
Epilimnion	The uppermost layer of water in a lake, characterised by an essentially uniform temperature that is generally warmer than elsewhere in the lake, and by relatively uniform mixing by wind and wave action.
Epilithon	Organisms attached to rocks, such as algae and lichens.
Epiphyte	A plant that grows on the outside of another plant, using it for support only and not obtaining food from it.

Eukaryotes	An organism characterised by the presence of membrane-bound organelles. See also Prokaryote.
Euphotic	Of surface waters to a depth of approximately 80–100 m; the lit region that extends virtually from the water surface to the level at which photosynthesis fails to occur because of reduced light penetration.
Euryhaline	Describes organisms that are capable of osmoregulating over a wide range of salinities.
Eutrophic	Abundant in nutrients and having high rates of productivity frequently resulting in oxygen depletion below the surface layer of a water body.
Eutrophication	Enrichment of waters with nutrients, primarily phosphorus, causing abundant aquatic plant growth and often leading to seasonal and/or diurnal deficiencies in dissolved oxygen.
Fate	Disposition of a material in various environmental compartments (e.g. soil or sediment, water, air, biota) as a result of transport, transformation and degradation.
Flocculation	<ul style="list-style-type: none"> <li>• The process by which suspended colloidal or very fine particles coalesce and agglomerate into well-defined hydrated floccules of sufficient size to settle rapidly.</li> <li>• The stirring of water after coagulant chemicals have been added to promote the formation of particles that will settle.</li> </ul>
Flow-through system	An exposure system for aquatic toxicity tests in which the test material solutions and control water flow into and out of test chambers on a once-through basis either intermittently or continuously.
Fouling	Accumulation of material through chemical, physical or biological processes.
Gastropod	A mollusc of the class Gastropoda, with a locomotive organ placed ventrally (e.g. snail and limpet).
Gross alpha (activity)	A measure of the concentration of alpha-particle emitting radionuclides in water. This is determined by standard techniques involving the evaporation of a water sample and measurement of the alpha activity of the residue.
Gross beta (activity)	A measure of the concentration of beta-particle emitting radionuclides in water. This is determined by standard techniques involving the evaporation of a water sample and measurement of the beta activity of the residue.
Groundwater	Water stored underground in rock crevices and in the pores of geologic materials that make up the earth's crust; water that supplies springs and wells. See also Aquifer.
Guideline trigger values	These are the concentrations (or loads) of the key performance indicators measured for the ecosystem, below which there exists a low risk that adverse biological (ecological) effects will occur. They indicate a risk of impact if exceeded and should 'trigger' some action, either further ecosystem specific investigations or implementation of management/remedial actions.
Guideline (water quality)	Numerical concentration limit or narrative statement recommended to support and maintain a designated water use.
Habitat	The place where a population (e.g. human, animal, plant, microorganism) lives and its surroundings, both living and non-living.
Half-life	Time required to reduce by one-half the concentration of a material in a medium (e.g. soil or water) or organism (e.g. fish tissue) by transport, degradation, transformation or depuration.

Hardness	The concentration of all metallic cations, except those of the alkali metals (e.g. sodium and potassium), present in water. In general, hardness is a measure of the concentration of calcium and magnesium ions in water and is frequently expressed as mg/L calcium carbonate equivalent.
Hazard	The potential or capacity of a known or potential environmental contaminant to cause adverse ecological effects.
High reliability guideline trigger values	Trigger values that have a higher degree of confidence because they are derived from an adequate set of chronic toxicity data and hence require less extrapolation from the data to protect ecosystems.
Humic substances	Organic substances only partially broken down that occur in water mainly in a colloidal state. Humic acids are large-molecule organic acids that dissolve in water.
Hydrolysis	<ul style="list-style-type: none"> <li>• The formation of an acid and a base from a salt by the ionic dissociation of water.</li> <li>• The decomposition of organic compounds by interaction with water.</li> </ul>
Hydrophilic	Having an affinity for water, readily absorbs water.
Hydrophobic	Having little or no affinity for water, repels or does not absorb water.
Hypolimnion	The region of a water body that extends from below the thermocline to the bottom of the lake; it is thus removed from much of the surface influence.
Hypothesis	Supposition made from known facts as a starting point for further investigation.
Hypoxia	Deficiency of oxygen in tissues or in blood; anoxia.
Indicator	A parameter that can be used to provide a measure of the quality of water or the condition of an ecosystem.
Inorganic carbon	Generally, simple ions and molecules that contain carbon bonded only to inorganic atoms. Carbonates are the most common group, although the cyanide ion is also considered to be inorganic.
Intermittent stream	A stream that carries water a considerable portion of the time, but that ceases to flow occasionally or seasonally because bed seepage and evapotranspiration exceed the available water supply.
Interstitial	Occurring in interstices or spaces; applied to water and to flora and fauna living between sand grains and soil particles.
Invertebrates	Animals lacking a dorsal column of vertebrae or a notochord.
In vitro	Outside the intact organism; generally applied to experiments involving biochemical events occurring in tissue fragments or fractions in a laboratory.
Ion	An electrically charged atom.
LC100	Lowest concentration of a toxicant that kills all the test organisms.
LC50	(or median lethal concentration) The concentration of material in water that is estimated to be lethal to 50% of the test organisms. The LC50 is usually expressed as a time-dependent exposure value, e.g. 24-hour or 96-hour LC50, the concentration estimated to be lethal to 50% of the test organisms after 24 or 96 hours of exposure.
LD50	(or median lethal dose) The dose of material that is estimated to be lethal to 50% of the test organisms. Appropriate for use with test animals such as rats, mice and dogs, it is rarely applicable to aquatic organisms because it indicates the quantity of a material introduced directly into the body by injection or ingestion rather than the concentration of the material in water in which aquatic organisms are exposed during toxicity tests.
Leachate	Water that has passed through a soil and that contains soluble material removed from that soil.

Lethal	Causing death by direct action. Death of aquatic organisms is the cessation of all visible signs of biological activity.
Level of protection	A level of quality desired by stakeholders and implied by the selected management goals and water quality objectives for the water resource.
Life-cycle study	A chronic (or full chronic) study in which all the significant life stages of an organism are exposed to a test material. Generally, a life-cycle test involves an entire reproductive cycle of the organism.
Live weight	Weight of the living animal.
LOEC	(or lowest observed effect concentration) The lowest concentration of a material used in a toxicity test that has a statistically significant adverse effect on the exposed population of test organisms as compared with the controls.
LOEL	(or lowest observed effect level) The lowest concentration that produces an observable effect in a test species. Below this concentration there are no observed effects in the test species.
Long-term trigger value (LTV)	The maximum concentration of contaminant in irrigation water which can be tolerated assuming 100 years of irrigation, based on key irrigation loading assumptions.
Low reliability guideline trigger values	Trigger values that have a low degree of confidence because they are derived from an incomplete data set. They are derived using either assessment factors or from modelled data using the statistical method. They should only be used as interim indicative working levels.
Macrophyte	A member of the macroscopic plant life of an area, especially of a body of water; large aquatic plant.
Median	Middle value in a sequence of numbers.
Mesotrophic	Water bodies or organisms which are intermediate between nutrient-rich and nutrient-poor.
Metabolite	Any product of metabolism.
Mixing zones	An explicitly defined area around an effluent discharge where effluent concentrations may exceed guideline values and therefore result in certain environmental values not being protected. The size of the mixing zone is site-specific.
Moderate reliability guideline trigger values	Trigger values that have a moderate degree of confidence because they are derived from an adequate set of acute toxicity data and hence require more extrapolation than high reliability trigger values, including an acute-to-chronic conversion.
Neurotoxin	Toxic substances which adversely affect the nervous system.
NOEC	(or no observed effect concentration) The highest concentration of a toxicant at which no statistically significant effect is observable, compared to the controls; the statistical significance is measured at the 95% confidence level. Not detectable or below the limit of detection of a specified method of analysis.
Octanol: water partition coefficient (Kow)	The ratio of a chemical's solubilities in n-octanol and water at equilibrium. Kow is used as an indication of a chemical's propensity for bioconcentration by aquatic organisms where n-octanol is a surrogate for typical animal lipid. The symbol Pow is sometimes used in place of Kow but they are alternative names for the same equilibrium solubility ratio.
Oligotrophic	Waters with a small supply of nutrients.
Organic carbon	Generally carbon which is chemically bonded to other carbon atoms, although methane (one carbon atom only) and its derivatives are considered organic.
Organism	Any living animal or plant; anything capable of carrying on life processes.

Osmoregulation	The biological process of maintaining the proper salt concentration in body tissues to support life.
Osmosis	Diffusion of a solvent through a semi-permeable membrane into a more concentrated solution, tending to equalise the concentrations on both sides of the membrane.
Oxidation	The combination of oxygen with a substance, or the removal of hydrogen from it or, more generally, any reaction in which an atom loses electrons.
Oxygenation	The process of adding dissolved oxygen to a solution.
PAH	Polycyclic aromatic hydrocarbons.
Parameter	A measurable or quantifiable characteristic or feature.
Partition coefficient	A ratio of the equilibrium concentration of the chemical between media, for example, between a non-polar and polar solvent, or between air and water, or water and sediment.
Pathogen	An organism capable of eliciting disease symptoms in another organism.
Pelagic	Term applied to organisms which inhabit the open seas and oceans.
Percentile	Division of a frequency distribution into one hundredths.
Periphyton	The organisms attached to submerged plants.
Pesticide	A substance or mixture of substances used to kill unwanted species of plants or animals.
pH	Value that represents the acidity or alkalinity of an aqueous solution. It is defined as the negative logarithm of the hydrogen ion concentration of the solution.
Photodegradation	Breakdown of a substance by exposure to light; the process whereby ultra-violet radiation in sunlight attacks a chemical bond or link in a chemical structure.
Photolysis	The decomposition of a compound into simpler units as a result of the absorption of one or more quanta of radiation.
Photosynthesis	The conversion of carbon dioxide to carbohydrates in the presence of chlorophyll using light energy.
Physico-chemical	Refers to the physical (e.g. temperature, electrical conductivity) and chemical (e.g. concentrations of nitrate, mercury) characteristics of water.
Phytoplankton	Small (often microscopic) aquatic plants suspended in water.
Phytotoxicity	Toxicity of contaminants to plants.
Plankton	Plants (phytoplankton) and animals (zooplankton), usually microscopic, floating in aquatic systems.
Pollution	The introduction of unwanted components into waters, air or soil, usually as a result of human activity, e.g. hot water in rivers, sewage in the sea, oil on land.
Polychlorinated biphenyls (PCBs)	Highly toxic and persistent compounds derived from the replacement of numerous H radicals by Cl radicals on biphenyl, which consists of two benzene rings joined by a covalent bond, with the elimination of two H radicals (C <sub>12</sub> H <sub>10</sub> ).
Potable water	Water suitable, on the basis of both health and aesthetic considerations, for drinking or culinary purposes.
Practical quantitation limit (PQL)	The best level achievable among laboratories within specified limits during routine laboratory operations. The PQL represents a practical and routinely achievable detection level with a relatively good certainty that any reported value is reliable. The PQL is often around five times the method detection limit.

Precipitation	<ul style="list-style-type: none"> <li>• The formation of solid particles in a solution; generally, the settling out of small particles.</li> <li>• The settling-out of water from cloud, in the form of rain, hail, snow, etc.</li> </ul>
Primary production	The production of organic matter from inorganic materials.
Producers	Organisms that are able to build up their body substance from inorganic materials.
Prokaryotes	Organisms characterised by the absence of membrane-bound organelles (opposite to eukaryotes).
Protocol	A formally agreed method and procedure for measuring an indicator; it defines the sampling, sample handling and sample analysis procedures.
Protozoans	Single-celled, animal-like organisms of the kingdom Protista.
Quality assurance (QA)	The implementation of checks on the success of quality control (e.g. replicate samples, analysis of samples of known concentration).
Quality control (QC)	The implementation of procedures to maximise the integrity of monitoring data (e.g. cleaning procedures, contamination avoidance, sample preservation methods).
Redox potential	An expression of the oxidising or reducing power of a solution relative to a reference potential. Redox potential is dependent on the nature of the substances dissolved in the water, as well as on the proportion of their oxidised and reduced components.
Reference condition	An environmental quality or condition that is defined from as many similar systems as possible and used as a benchmark for determining the environmental quality or condition to be achieved and/or maintained in a particular system of equivalent type.
Release of water	Water freed from a site for specified purposes such as disposal. May occur by means of infrastructure such as a constructed channel or pipe, or by a natural flow pathway such as an overland gully or drainline.
Residence time	The period of time that a volume of liquid (and any associated contaminants) remains in a waterway, catchment system, creek bed, or a part thereof.
Salinity	The presence of soluble salts in or on soils or in water.
Sediment	Unconsolidated mineral and organic particulate material that settles to the bottom of aquatic environment.
Sediment pore waters	Water that occupies the space between particles in a sediment, as distinct from overlying water which is the water above the sediment layer.
Sewage fungus	A thick filamentous bacterial growth that develops in water contaminated with sewage. The filamentous material is composed predominately of the bacterium <i>Sphaerotilus natans</i> .
Short-term trigger value (LTV)	The maximum concentration of contaminant in irrigation water which can be tolerated for a shorter period of time (20 years) assuming the same maximum annual irrigation loading to soil as for the long-term trigger value.
Sodicity	The presence of a high proportion of sodium ions relative to other cations in a soil.
Sorption	Process whereby contaminants in soils adhere to the inorganic and organic soil particles.
Speciation	The distribution of an element among defined chemical forms, for example, valency or organic and inorganic forms.

Species	A group of organisms that resemble each other to a greater degree than members of other groups and that form a reproductively isolated group that will not produce viable offspring if bred with members of another group.
Species richness	The number of species present (generally applied to a sample or community).
Suspended particulate matter (SPM)	This is insoluble material which resides in the water column, or is dispersed in a sample upon agitation.
Standard (water quality)	An objective that is recognised in enforceable environmental control laws.
Sub-lethal	Involving a stimulus below the level that causes death.
Supersaturation	Refers to a solution containing more solute than equilibrium conditions will allow.
Synergism	A phenomenon in which the effect or toxicity of a mixture of chemicals is greater than that to be expected from a simple summation of the effects or toxicities of the individual chemicals summation of the effects or toxicities of the individual chemicals present in the mixture.
Teratogen	An agent that increases the incidence of congenital malformations.
Thermotolerant coliforms	Also known as faecal coliforms. In tropical and sub-tropical areas, thermotolerant coliforms may on some occasions include microorganisms of environmental rather than faecal origin.
Threshold concentration	A concentration above which some effect (or response) will be produced and below which it will not.
Total dissolved solids (TDS)	A measure of the inorganic salts (and organic compounds) dissolved in water.
Total metal	The concentration of a metal in an unfiltered sample that is digested in strong nitric acid.
Toxicant	A chemical capable of producing an adverse response (effect) in a biological system at concentrations that might be encountered in the environment, seriously injuring structure or function or producing death. Examples include biocides, pesticides and biotoxins (i.e. domoic acid, ciguatoxin and saxitoxins).
Toxicity	The inherent potential or capacity of a material to cause adverse effects in a living organism.
Toxicity identification and evaluation (TIE)	Toxicity characterisation procedures involving use of selective chemical manipulations or separations and analyses coupled with toxicity testing to identify specific classes of chemicals and ultimately individual chemicals that are responsible for the toxicity observed in a particular sample.
Toxicity test	The means by which the toxicity of a chemical or other test material is determined. A toxicity test is used to measure the degree of response produced by exposure to a specific level of stimulus (or concentration of chemical).
Trigger values	These are the concentrations (or loads) of the key performance indicators measured for the ecosystem, below which there exists a low risk that adverse biological (ecological) effects will occur. They indicate a risk of impact if exceeded and should 'trigger' some action, either further ecosystem-specific investigations or implementation of management/remedial actions.
Volatile	Having a low boiling or subliming pressure (a high vapour pressure).
Water quality criteria	Scientific data evaluated to derive the recommended quality of water for various uses.

Water quality objective	A numerical concentration limit or narrative statement that has been established to support and protect the designated uses of water at a specified site. It is based on scientific criteria or water quality guidelines but may be modified by other inputs such as social or political constraints.
Wastewater	Water that has been adversely affected in quality by anthropogenic influence such as use in a washing, flushing, or manufacturing process.
Watertable	The level of groundwater; the upper surface of the zone of saturation for underground water.
Whole effluent toxicity testing (WET testing)	See Direct toxicity assessment.
Xenobiotic	A foreign chemical or material not produced in nature and not normally considered a constituent of a specified biological system. This term is usually applied to manufactured chemicals.
Zooplankton	The animal portion of the plankton.

# Final Model Water Conditions for Coal Mines in the Fitzroy Basin

**Note:**

Explanatory notes are in green. DELETE prior to issue of EA.

Insertions required by applicants and or the administering authority are in blue. DELETE prior to issue.

**Contaminant Release**

- W1** Contaminants that will, or have the potential to cause environmental harm must not be released directly or indirectly to any waters except as permitted under the conditions of this environmental authority.
- W2** The release of contaminants to waters must only occur from the release points specified in Table 1 and depicted in Figure 1 <this would be a plan or plans locating all monitoring (water quality and flow) and release points> attached to this environmental authority.

**Table 1 (Contaminant Release Points, Sources and Receiving Waters)**

Release Point (RP)	Latitude or northing (GDA94)	Longitude or easting (GDA94)	Contaminant Source and Location	Monitoring Point	Receiving waters description
RP 1	XXXX	XXXX	e.g. Stormwater Dam Spillway Overflow	Dam Spillway	Wet Creek
RP 2	XXXX	XXXX	e.g. Dam overflow pipe	Sampling Tap on pipe where the pipe enters Sandy Creek	Sandy Creek

- W3** The release of contaminants to waters must not exceed the release limits stated in Table 2 when measured at the monitoring points specified in Table 1 for each quality characteristic.

**Table 2 (Contaminant Release Limits)**

**EXPLANATORY NOTES – Setting interim release limits for EC:**

Option (c) – To negotiate a higher value for end-of-pipe EC limits, it will be necessary to have sufficient background water quality data from historical flow events, ideally above each discharge point. This data should be used to demonstrate that there is sufficient “assimilative capacity” in receiving waters to receive mine discharges of the proposed higher EC levels and maximum flows specified in condition W9. In other words, the limits should be such that the predicted in-stream water quality downstream will always remain below 1000 µS/cm EC (for example, using all historical data and assumptions of complete dilution). Consideration should also be given to the potential impact on any drinking water reservoirs immediately downstream of the discharge and the need to keep in-stream water quality below 750 µS/cm.

Option (d) – To negotiate a stepped approach to achieve Option (b) or (c) it will be necessary to predict the likely downstream receiving water EC as a result of the proposed limits for each step proposed. It will be necessary to have sufficient background water quality data from historical flow events, ideally for each discharge point. The data should be used to demonstrate that there is sufficient assimilative capacity to receive mine discharges of the proposed higher EC levels and maximum flows specified in condition W9. The limits should be such that predicted the in-stream water quality downstream is not likely to result in environmental harm from high salinity impacts. Ideally, in-stream EC s should remain below 1000 µS/cm EC (for example, using all historical data and assumptions of complete dilution). Where in-stream EC is likely to be above 1000 µS/cm then a case should be put forward as to why this is required and comments about the likelihood and potential extent of impacts. Consideration should also be given to the potential impact on any drinking water reservoirs immediately downstream of the discharge and the need to keep in-stream water quality below 750 µS/cm.

Quality Characteristic	Interim Release Limits for all mines (limits to apply from the date of issue)	Future Release Limits from XX/XX/XXXX (negotiated date) <b>Note:</b> These future limits will apply from a yet to be negotiated date using alternative numbers that will be derived from the information gathered by any combination of the following: (1) the results of near field monitoring, (2) any studies or investigations carried out in accordance with recommendations 2 & 3 of the Cumulative Impact Study on water quality in the Fitzroy River Basin. (3) any review of the QLD Water Quality Guidelines. (4) other relevant information <b>Note:</b> This information should be available by the end of 2011 if not before and when it becomes available limits will be determined for each mine site based on the environmental values to be protected and in accordance with criteria below	Monitoring frequency	Comment
Electrical conductivity (uS/cm)	<p>Hierarchy for determining limits in priority order starting with (a):</p> <p>(a) for mines that do not release contaminants to waters - no conditions are required for release authorisation, then conditions W2, to W15 inclusive, W18, W19 and W43 can be deleted.</p> <p>(b) Current limit for those mine sites not under a TEP or 1500 EC (Maximum)* which ever is lower or</p> <p>(c) a negotiated higher limit value that does not result in the contaminant release exceeding a maximum 1000 EC in the receiving waters and where the mine site demonstrates to DERM that it is unreasonable and impractical to immediately comply with the 1500 EC limit in (b) above and supported by a business case and commitment to ongoing environmental improvement on the mine site and with nominated timeframes.</p> <p><i>Note: If the current limit is lower than a limit determined as above then the current limit would initially apply.</i></p> <p>(d) for those other mines which cannot immediately achieve (b) or (c) above a stepped approach within the interim period ending 2011 to achieve (b) or (c) will be</p>	<p><b>Aquatic ecosystem protection (no drinking water value):</b></p> <p>An end-of-pipe limit to achieve in the range 0 to 1000 EC in the receiving waters. (Must have natural flow i.e. the 20<sup>th</sup> percentile flow trigger and achieve a 1:4 dilution</p> <p><b>OR</b></p> <p>for mines in the upper catchments must have natural flow i.e. the 20<sup>th</sup> percentile flow trigger.</p> <p><b>OR</b></p> <p><b>Drinking water protection:</b></p> <p>An end-of-pipe limit to achieve 0 to 750 EC in the receiving waters. (Must have natural flow, either 1:4 dilution and only release where a 20<sup>th</sup> percentile flow trigger occurs; OR for mines in the upper catchment must have a natural flow i.e. 20<sup>th</sup> percentile trigger.</p>	Daily during release (the first sample must be taken within 2 hours of commencement of release)	

	<p>required.</p> <p><i>Note: some of these mines may already be under an approved TEP and EC limits and compliance timeframes in the TEP need to be taken into account with the stepped approach.</i></p> <p>To support a stepped approach DERM will require a business case and commitment to ongoing environmental improvement on the mine site to ensure that all reasonable and practicable measures are being/will be taken to prevent and/or minimise environmental harm.</p>			
pH (pH Unit)	<p>6.5 (minimum)</p> <p>9.0 (maximum)</p>	<p>6.5 (minimum)</p> <p>9.0 (maximum)</p>	Daily during release (the first sample must be taken within 2 hours of commencement of release)	
Turbidity (NTU)	NA*	NA*	Daily during release* (first sample within 2 hours of commencement of release)	Turbidity is required to assess ecosystems impacts and can provide instantaneous results.
Suspended Solids (mg/L)	Current Limit	Limit to be determined based on receiving water reference data and achievable best practice sedimentation control and treatment	Daily during release* (first sample within 2 hours of commencement of release)	Suspended solids are required to measure the performance of sediment and erosion control measures.
Sulphate (SO <sub>4</sub> <sup>2-</sup> ) (mg/L)	Current limit or 1000 (maximum) which ever is the lower	<p>250 (Maximum) (Protection of drinking water Environmental Value)</p> <p>OR</p> <p>1000 (Maximum) (Protection of irrigation environmental value)</p>	Daily during release* (first sample within 2 hours of commencement of release)	Drinking water environmental values from NHMRC 2006 guidelines OR ANZECC & ARMCANZ 2000 stock water quality guidelines.

Note: NA – not available, \* local trigger values need to be developed

**W4** The release of contaminants to waters from the release points must be monitored at the locations specified in Table 1 for each quality characteristics and at the frequency specified in Table 2 and Table 3.

**Table 3 (Release Contaminant Trigger Investigation Levels)**

Quality Characteristic	Trigger Levels (µg/L)	Comment on Trigger Level	Monitoring Frequency
Aluminium	100	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>	Commencement of release and thereafter weekly during release
Arsenic	13	<i>For aquatic ecosystem protection, based on SMD guideline</i>	
Cadmium	0.2	<i>For aquatic ecosystem protection, based on SMD guideline</i>	
Chromium	1	<i>For aquatic ecosystem protection, based on SMD guideline</i>	
Copper	2	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>	
Iron	300	<i>For aquatic ecosystem protection, based on low reliability guideline</i>	
Lead	10	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>	
Mercury	0.2	<i>For aquatic ecosystem protection, based on LOR for CV FIMS</i>	
Nickel	11	<i>For aquatic ecosystem protection, based on SMD guideline</i>	
Zinc	8	<i>For aquatic ecosystem protection, based on SMD guideline</i>	
Include additional contaminants as required	Include additional contaminants as required		

**EXPLANATORY NOTES – Table 3 Potential Contaminants:**

The quality characteristics listed below should be assessed on a site by site basis by each mine prior to finalisation of amendment applications. Based on this assessment, the quality characteristic should be either disregarded if below trigger levels; or included as priority contaminants in Table 3 if above trigger levels. Assessment should involve comparison of representative data from dams that have historically been discharged or likely to be discharged from contaminant release points in Table 1. Data may include historical results or sampling undertaken for this specific purpose. The intent here is that not all dams on site would need to be sampled but those that would make up the majority of water in dams with release points. It could also be demonstrated based on existing water quality information that the water source and relative water quality of some dam are the same, in which case such dams may not need to be sampled individually. For metals and metalloids, trigger levels apply if dissolved results exceed trigger levels. However, total (unfiltered) results for metals and metalloids can be used to disregard a characteristic for inclusion in Table 3. Terms include SMD – slightly moderately disturbed level of protection, guideline - refers ANZECC & ARMCANZ (2000), LOR – typical reporting for method stated. ICPMS/CV FIMS – analytical methods required to achieve LOR.

**Table 3 (Release Contaminant Trigger Investigation Levels) Potential Contaminants**

Quality Characteristic	Trigger Levels (µg/L)	Comment on Trigger Level
Boron	370	<i>For aquatic ecosystem protection, based on SMD guideline</i>
Cobalt	90	<i>For aquatic ecosystem protection, based on low reliability guideline</i>
Manganese	1900	<i>For aquatic ecosystem protection, based on SMD guideline</i>
Molybdenum	34	<i>For aquatic ecosystem protection, based on low reliability guideline</i>
Selenium	10	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>
Silver	1	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>
Uranium	1	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>

Vanadium	10	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>
Ammonia	900	<i>For aquatic ecosystem protection, based on SMD guideline</i>
Nitrate	1100	<i>For aquatic ecosystem protection, based on ambient Qld WQ Guidelines (2006) for TN</i>
Petroleum hydrocarbons (C6-C9)	20	
Petroleum hydrocarbons (C10-C36)	100	
Fluoride (total)	2000	<i>Protection of livestock and short term irrigation guideline</i>

**Note:**

1. All metals and metalloids must be measured as total (unfiltered) and dissolved (filtered). Trigger levels for metal/metalloids apply if dissolved results exceed trigger.
2. The list of quality characteristics required to be monitored as per Table 3 will be reviewed once the results of the monitoring data is gathered for the interim period until 31 December 2011 or an earlier date if the data is, or becomes, available and if it is determined that there is no need to monitor for certain individual quality characteristics these can be removed from Table 3.
3. SMD – slightly moderately disturbed level of protection, guideline refers ANZECC & ARMCANZ (2000).
4. LOR – typical reporting for method stated. ICPMS/CV FIMS – analytical method required to achieve LOR.

**W5** If quality characteristics of the release exceed any of the trigger levels specified in Table 3 during a release event, the environmental authority holder must compare the down stream results in the receiving waters to the trigger values specified in Table 3 and:

1. where the trigger values are not exceeded then no action is to be taken; or
2. where the down stream results exceed the trigger values specified Table 3 for any quality characteristic, compare the results of the down stream site to the data from background monitoring sites and;
  - (a) if the result is less than the background monitoring site data, then no action is to be taken; or
  - (b) if the result is greater than the background monitoring site data, complete an investigation in accordance with the ANZECC & ARMCANZ 2000 methodology, into the potential for environmental harm and provide a written report to the administering authority in the next annual return, outlining:
    - (i) details of the investigations carried out; and
    - (ii) actions taken to prevent environmental harm.

*Note: Where an exceedance of a trigger level has occurred and is being investigated, in accordance with W5 2(b)(ii) of this condition, no further reporting is required for subsequent trigger events for that quality characteristic.*

**W6** If an exceedance in accordance with condition W5 2(b)(ii) is identified, the holder of the authority must notify the administering authority within 14 days of receiving the result.

**Contaminant Release Events**

**W7** The holder must install, operate and maintain a stream flow gauging station to determine and record stream flows at the locations upstream of each Release Point as specified in Table 4 for any receiving water into which a release occurs.

**W8** Notwithstanding any other condition of this environmental authority, the release of contaminants to waters must only take place during periods of natural flow events specified as minimum flow in Table 4 for the contaminant release point(s) specified in Table 1.

**Table 4 (Contaminant Release during Flow Events)**

**EXPLANATORY NOTES – Table 4**

**Gauging station description:**

The intent here is that every release point in Table 1 is associated with a gauging station that measures flow upstream of the discharge point. More than one discharge point may be associated with the same gauging station. The gauging station should be at a minimum distance from the discharge point such that water flow under trigger flow events will not significantly diminish by the time it reaches the discharge point. The location of the gauging station should ideally be such that it is not significantly affected by other upstream point source releases or times of discharge are limited to periods of “natural” flow.

Under certain circumstances it may be appropriate to have a downstream gauging station in addition to or in replace of an upstream gauging station. The location should ideally not be affected by the discharge (e.g. be measured off the main waterway). The need for this must be demonstrated on a case by case basis to show why an upstream gauging station is insufficient. This may be the case when mines are located in the upper parts of catchments or near the downstream confluence or a major waterway. Similarly, the gauging station should be at a distance from the discharge point such that water flow during triggered flow events will not significantly diminish between the discharge point and the measuring point (or the confluence with the creek being measured). For downstream flow triggers, some changes to calculation for flow triggers and maximum release flows would typically be required based on the relative sizes of the waterways involved.

**Minimum Flow Trigger:**

The intent for the minimum flow trigger is that the times of discharge are limited to times of natural flow events only (for ephemeral receiving waters). Ideally, the flow trigger should be chosen such that it represents, for example, a 20<sup>th</sup> percentile average daily flow (in m<sup>3</sup>/s) of a minimum ten year period. This or a similar approach should aim to eliminate discharges during “low flow” periods. The maximum discharge volume can then be calculated by dividing the upstream flow trigger by 4. The intent here is that a minimum dilution 1:4 is always maintained (20% of downstream flow). In some situations, this will not allow the mine to release sufficient quantities of water. Therefore, it is possible to propose more than one flow trigger. For example, a 40<sup>th</sup> percentile average daily flow trigger may also be used in addition to the initial 20<sup>th</sup> percentile flow trigger such that above the 40<sup>th</sup> percentile average daily flow trigger a higher release volume will be allowed during periods of higher in-stream flow (while still maintaining a 1:4 dilution ratio).

The expectation is that where flow gauging data is available, it is used to calculate flow triggers. Where gauging data is not available or is insufficient, flow triggers should be based on runoff/stream flow estimates using appropriate hydrological calculations or models and known catchment area, rainfall estimations etc.

Under certain circumstances, such as where a mine is in the upper part of the catchment, achieving a 1:4 dilution with receiving waters as described above may not allow the mine to discharge sufficient volumes. In such a case, a lower flow trigger must still be proposed but the discharge volume will also need to be linked to some downstream flow measure with sufficient dilution (ideally much greater than 1:4). The need for this must be demonstrated on a case by case basis and be supported by various flow calculations to demonstrate feasibility and show minimal environmental impacts.

Other special cases include discharges to creeks below water reservoirs or dams and these should be dealt with on a case by case basis to address the intent described above.

Receiving water description	Release Point	Gauging station description	Latitude or northing (GDA94)	Longitude or easting (GDA94)	Minimum Flow in Receiving Water Required for a Release Event	Flow recording Frequency
Wet Creek		Gauging station 1	XXXX	XXXX	Depending on individual catchment this minimum flow trigger will be either the release comprising less than 20% of the natural flow or any natural flow in the receiving environment. The volume of flow can be determined by height of water or flow. The actual flow must be a quantifiable measure. Example: > or = 5 m <sup>3</sup> /sec	Continuous (minimum daily)

- W9** Contaminant release flow rate must not exceed 20% of receiving water flow rate.
- W10** The daily quantity of contaminants released from each release point must be measured and recorded at the monitoring points in Table 1.
- W11** Releases to waters must be undertaken so as not to cause erosion of the bed and banks of the receiving waters, or cause a material build up of sediment in such waters.

#### **Notification of Release Event**

- W12** The authority holder must notify the administering authority as soon as practicable (no later than 6 hours of having commenced releasing mine affected water to the receiving environment). Notification must include the submission of written verification to the administering authority of the following information:
- release commencement date/time;
  - expected release cessation date/time;
  - release point/s;
  - release volume (estimated);
  - receiving water/s including the natural flow rate; and
  - any details (including available data) regarding likely impacts on the receiving water(s).

*Note: Notification to the administering authority must be addressed to the Manager and Project Manager of the local Administering Authority via email or facsimile.*

- W13** The authority holder must notify the administering authority as soon as practicable, (nominally within twenty-four (24) hours after of cessation of a release) of the cessation of a release notified under Condition W12 and within 28 days provide the following information in writing:
- release cessation date/time;
  - natural flow volume in receiving water;
  - volume of water released;
  - details regarding the compliance of the release with the conditions of Agency Interest: Water of this environmental authority (i.e. contamination limits, natural flow, discharge volume);
  - all in-situ water quality monitoring results; and
  - any other matters pertinent to the water release event.

#### **Notification of Release Event Exceedance**

- W14** If the release limits defined in Table 2 are exceeded, the holder of the environmental authority must notify the administering authority within twenty-four (24) hours of receiving the results.
- W15** The authority holder must, within twenty-eight (28) days of a release that exceeds the conditions of this authority, provide a report to the administering authority detailing:
- the reason for the release;
  - the location of the release;
  - all water quality monitoring results;
  - any general observations;
  - all calculations; and
  - any other matters pertinent to the water release event.

#### **Monitoring of Water Storage Quality**

- W16** Water storages stated in Table 5 which are associated with the release points must be monitored for the water quality characteristics specified in Table 6 at the monitoring locations and at the monitoring frequency specified in Table 5.

**Table 5 (Water Storage Monitoring)**

Water Storage Description	Latitude or northing (GDA94)	Longitude or easting (GDA94)	Monitoring Location	Frequency of Monitoring
XXXX	XXXX	XXXX	To be negotiated- will depend on the individual storage structure volume. This will deal with stratification – depth profiles and be appropriate to in situ quality characteristics.	Quarterly

**W17** In the event that waters storages defined in Table 5 exceed the contaminant limits defined in Table 6, the holder of the environmental authority must implement measures, where practicable, to prevent access to waters by all livestock.

**Table 6 (Onsite Water Storage Contaminant Limits)**

Quality Characteristic	Test Value	Contaminant Limit
pH (pH unit)	Range	Greater than 4, less than 9 <sup>2</sup>
EC (µS/cm)	Maximum	5970 <sup>1</sup>
Sulphate (mg/L)	Maximum	1000 <sup>1</sup>
Fluoride (mg/L)	Maximum	2 <sup>1</sup>
Aluminium (mg/L)	Maximum	5 <sup>1</sup>
Arsenic (mg/L)	Maximum	0.5 <sup>1</sup>
Cadmium (mg/L)	Maximum	0.01 <sup>1</sup>
Cobalt (mg/L)	Maximum	1 <sup>1</sup>
Copper (mg/L)	Maximum	1 <sup>1</sup>
Lead (mg/L)	Maximum	0.1 <sup>1</sup>
Nickel (mg/L)	Maximum	1 <sup>1</sup>
Zinc (mg/L)	Maximum	20 <sup>1</sup>

Note:

<sup>1</sup> Contaminant limit based on ANZECC & ARMCANZ (2000) stock water quality guidelines.

<sup>2</sup> Page 4.2-15 of ANZECC & ARMCANZ (2000) "Soil and animal health will not generally be affected by water with pH in the range of 4–9".

Note: Total measurements (unfiltered) must be taken and analysed

### Receiving Environment Monitoring and Contaminant Trigger Levels

**W18** The quality of the receiving waters must be monitored at the locations specified in Table 8 for each quality characteristic and at the monitoring frequency stated in Table 7.

**Table 7 (Receiving Waters Contaminant Trigger Levels)**

Quality Characteristic	Trigger Level	Monitoring Frequency	Comments
pH	6.5 – 8.0	Daily during the release	<b>See Table 2 comments</b>
Electrical Conductivity (µS/cm)	1000		
Suspended solids (mg/L)	To Be Determined. Turbidity may be required to assess ecosystems impacts and can provide instantaneous results.		
Sulphate (SO <sub>4</sub> <sup>2-</sup> ) (mg/L)	250 (Protection of drinking water Environmental Value) OR 1000 (Protection of irrigation environmental value)		

**Table 8 (Receiving Water Upstream Background Sites and Down Stream Monitoring Points)**

**EXPLANATORY NOTES – Selection of monitoring sites:**

The intent here is that that each discharge point has both an upstream and downstream monitoring point associated with it. These monitoring points should be located as close as practicable to the release point and the distances should be defined in the footnotes in Table 8. The location of flow monitoring points should also be considered in selecting upstream monitoring points. Other considerations include accessibility, particularly during wet weather conditions.

Monitoring Points	Receiving Waters Location Description	Latitude or northing (GDA94)	Longitude or easting (GDA94)
Upstream Background Monitoring Points			
Monitoring Point XX	XXXX Creek XX metres upstream of RP XX	XXXX	XXXX
Monitoring Point XX	XXXX Creek XX metres upstream of RP XX	XXXX	XXXX
Downstream Monitoring Points			
Monitoring Point XX	XXXX Creek XX metres downstream of RP XX	XXXX	XXXX
Monitoring Point XX	XXXX Creek XX metres downstream of RP XX	XXXX	XXXX

*Notes:*

- a) The upstream monitoring point should be within Xkm the release point.
- b) the downstream point should not be greater than Xm from the release point.
- c) The data from background monitoring points must not be used where they are affected by releases from other mines.

**W19** If quality characteristics of the receiving water at the downstream monitoring points exceed any of the trigger levels specified in Table 7 during a release event the environmental authority holder must compare the down stream results to the upstream results in the receiving waters and:

1. where the downstream result is the same or a lower value than the upstream value for the quality characteristic then no action is to be taken; or

2. where the down stream results exceed the upstream results complete an investigation in accordance with the ANZECC & ARMCANZ 2000 methodology, into the potential for environmental harm and provide a written report to the administering authority in the next annual return, outlining:
  - (i) details of the investigations carried out; and
  - (ii) actions taken to prevent environmental harm.

*Note: Where an exceedance of a trigger level has occurred and is being investigated, in accordance with W19 2(ii) of this condition, no further reporting is required for subsequent trigger events for that quality characteristic.*

## Receiving Environment Monitoring Program (REMP)

---

### EXPLANATORY NOTES – Designing a REMP:

The intent here is that the REMP will be designed for specific requirements of the mine's releases and the receiving environment. The monitoring within the REMP should not be the primary basis for compliance but will be essential for providing supporting information when incidents may occur or for deriving future license limits. The focus should also be on reporting against water quality objectives for relevant waterways affected by the discharge and be on a longer term basis compared to compliance reporting. The intent is that the REMP is to provide condition assessment of near-field areas, ie. local areas likely to be significantly affected by the mine's releases. To do this, it is necessary that monitoring data is collected during times of natural flow outside of times of release in addition to time of release. The REMP is likely to include monitoring sites and indicators in addition to what is presented in the tables of these conditions. The intent is that far-field areas and cumulative impacts will be monitored as part of regional monitoring described in Condition W43 and assist in providing regional condition assessment and regionally specific reference information.

---

**W20** A REMP must be developed and implemented by XX/XX/XXXX (WITHIN 3 MONTHS OF THE DATE OF ISSUE) to monitor and record the effects of the release of contaminants on the receiving environment periodically and whilst contaminants are being discharged from the site, with the aims of identifying and describing the extent of any adverse impacts to local environmental values, and monitoring any changes in the receiving water. A copy of the REMP must be provided to the administering authority prior to its implementation and due consideration given to any comments made on the REMP by the administering authority.

For the purposes of the REMP, the receiving environment is the waters of the XX and connected waterways within XX (e.g. Xkm) downstream of the release.

**W21** The REMP must address (but not necessarily be limited to) the following:

- a) Description of potentially affected receiving waters including key communities and background water quality characteristics based on accurate and reliable monitoring data that takes into consideration any temporal variation (e.g. seasonality); and
- b) Description of applicable environmental values and water quality objectives to be achieved (i.e. as scheduled pursuant to the Environmental Protection (Water) Policy 1997); and
- c) Any relevant reports prepared by other governmental or professional research organisations that relate to the receiving environment within which the REMP is proposed; and
- d) Water quality targets within the receiving environment to be achieved, and clarification of contaminant concentrations or levels indicating adverse environmental impacts during the REMP.
- e) Monitoring for any potential adverse environmental impacts caused by the release;
- f) Monitoring of stream flow and hydrology;
- g) Monitoring of toxicants should consider the indicators specified in Table 3 to assess the extent of the compliance of concentrations with water quality objectives and/or the ANZECC & ARMCANZ 2000 guidelines for slightly to moderately disturbed ecosystems;
- h) Monitoring of physical chemical parameters as a minimum those specified in Table 2 (in addition to dissolved oxygen saturation and temperature);
- i) Monitoring biological indicators (for macroinvertebrates in accordance with the AusRivas methodology) and metals/metalloids in sediments (in accordance with ANZECC & ARMCANZ 2000, BATLEY and/or the most recent version of AS5667.1 *Guidance on Sampling of Bottom Sediments*) for permanent, semi-permanent water holes and water storages;

- j) The locations of monitoring points (including the locations specified in Table 8 which are background and downstream impacted sites for each release point);
- k) The frequency or scheduling of sampling and analysis sufficient to determine water quality objectives and to derive site specific reference values within 2 years (depending on wet season flows) in accordance with the *Queensland Water Quality Guidelines 2006*. For ephemeral streams, this should include periods of flow irrespective of mine or other discharges;
- l) Specify sampling and analysis methods and quality assurance and control;
- m) Any historical datasets to be relied upon;
- n) Description of the statistical basis on which conclusions are drawn, and
- o) Any spatial and temporal controls to exclude potential confounding factors.

**W22** A report outlining the findings of the REMP, including all monitoring results and interpretations in accordance with conditions W20 must be prepared and submitted in writing to the administering authority by 1 October 2011. This should include an assessment of background water quality, any assimilative capacity for those contaminants monitored and the suitability of current discharge limits to protect downstream environment values.

### Water Reuse

**W23** Water contaminated by mining activity may be piped or trucked or transferred by some other means that does not contravene the conditions of this authority during periods of dry weather for the purpose of supplying stock water to properties directly adjoining properties owned by the environmental authority holder or a third party and subject to compliance with the quality release limits specified in Table 9.

**Table 9 (Stock Water Release Limits)**

Quality characteristic	Units	Minimum	Maximum
pH	pH units	6.5	8.5
Electrical Conductivity	µS/cm	N/A	5000

**W24** Water contaminated by mining activity may be piped or trucked or transferred by some other means that does not contravene the conditions of this authority during periods of dry weather for the purpose of supplying irrigation water to properties directly adjoining properties owned by the environmental authority holder or a third party and subject to compliance with quality release limits in Table 10.

**Table 10 (Irrigation Water Release Limits)**

Quality characteristic	Units	Minimum	Maximum
pH	pH units	6.5	8.5
Electrical Conductivity	µS/cm	N/A	Site specific value to be determined in accordance with ANZECC & ARMCANZ (2000) Irrigation Guidelines

**W25** Water contaminated by mining activity may be piped or trucked off the mining lease for the purpose of supplying water to a third party for purpose of construction and/or road maintenance in accordance with the conditions of this environmental authority.

**W26** Water contaminated by mining activity may be piped or trucked for the purpose of supplying water to <name adjoining mine> in accordance with the conditions of this environmental authority. The volume, pH and electrical conductivity of water transferred to {name adjoining mine} must be monitored and recorded.

**W27** If the responsibility of water contaminated by mining activities (the water) is given or transferred to another person in accordance with conditions **W23, W24, W25 or W26:**

- a) the responsibility of the water must only be given or transferred in accordance with a written agreement (the third party agreement); and

- b) include in the third party agreement a commitment from the person utilising the water to use water in such a way as to prevent environmental harm or public health incidences and specifically make the persons aware of the General Environmental Duty (GED) under section 319 of the *Environmental Protection Act 1994*, environmental sustainability of the water disposal and protection of environmental values of waters.

### Water General

**W28** All determinations of water quality must be:

- a) performed by a person or body possessing appropriate experience and qualifications to perform the required measurements;
- b) made in accordance with methods prescribed in the latest edition of the Environment Protection Agency Water Quality Sampling Manual;

*Note: Condition W28 requires the Water Quality Manual to be followed and where it is not followed because of exceptional circumstances this should be explained and reported with the results.*

- c) collected from the monitoring locations identified within this environmental authority, within XX hour of each other where possible; and
- d) carried out on representative samples.
- e) **laboratory testing must be undertaken using a laboratory accredited (e.g. NATA) for the method of analysis being used.**

**W29** The release of contaminants directly or indirectly to waters:

- a) must not produce any visible discolouration of receiving waters; nor
- b) must not produce any slick or other visible or odorous evidence of oil, grease or petrochemicals nor contain visible floating oil, grease, scum, litter or other objectionable matter.

### Annual Water Monitoring Reporting

**W30** The following information must be recorded in relation to all water monitoring required under the conditions of this environmental authority and submitted to the administering authority in the specified format with each annual return:

- a) the date on which the sample was taken;
- b) the time at which the sample was taken;
- c) the monitoring point at which the sample was taken;
- d) the measured or estimated daily quantity of the contaminants released from all release points;
- e) the release flow rate at the time of sampling for each release point;
- f) the results of all monitoring and details of any exceedences with the conditions of this environmental authority; and
- g) water quality monitoring data must be provided to the administering authority in the specified electronic format upon request.

### Temporary Interference with waterways

**W31** Temporarily destroying native vegetation, excavating, or placing fill in a watercourse, lake or spring necessary for and associated with mining operations must be undertaken in accordance with Department of Natural Resources and Water *Guideline - Activities in a Watercourse, Lake or Spring associated with Mining Activities*.

### Water Management Plan

**W32** A Water Management Plan must be developed and implemented by **XX/XX/XXXX (WITHIN 3 MONTHS OF THE DATE OF ISSUE)** that provides for the proper and effective management of the actual and potential environmental impacts resulting from the mining activity and to ensure compliance with the conditions of this environmental authority.

**W33** The Water Management Plan must be developed in accordance with DERM Guideline for Preparing a Water Management Plan 2009 (**to be developed by 1 October**) or any updates that become available from time to time and must include at least the following components:

- a) Contaminant Source Study;
- b) Site Water Balance and Model;
- c) Water Management System;
- d) Saline Drainage Prevention and Management Measures;
- e) Acid Rock Drainage Prevention and Management Measures (if applicable);
- f) Emergency and Contingency Planning;
- g) Monitoring and Review.

**W34** Each year the holder of the environmental authority must undertake a review of the Water Management Plan prior to the wet season (i.e. by 1 November) and a further review following the wet season (i.e. by 1 May the following year) to ensure that proper and effective measures, practices or procedures are in place so that the mine is operated in accordance with the conditions of this environmental authority and that environmental harm is prevented or minimised.

**W35** A copy of the Water Management Plan and/or a review of the Water Management Plan must be provided to the administering authority on request.

### **Saline Drainage**

**W36** The holder of this environmental authority must ensure proper and effective measures are taken to avoid or otherwise minimise the generation and/or release of saline drainage.

### **Acid Rock Drainage**

**W37** The holder of this environmental authority must ensure proper and effective measures are taken to avoid or otherwise minimise the generation and/or release of acid rock drainage.

### **Stormwater and Water sediment controls**

**W38** An Erosion and Sediment Control Plan must be developed by an appropriately qualified person and implemented for all stages of the mining activities on the site to minimise erosion and the release of sediment to receiving waters and contamination of storm water.

**W39** The maintenance and cleaning of any vehicles, plant or equipment must not be carried out in areas from which contaminants can be released into any receiving waters.

**W40** Any spillage of wastes, contaminants or other materials must be cleaned up as quickly as practicable to minimise the release of wastes, contaminants or materials to any stormwater drainage system or receiving waters.

### **All Dams**

---

#### **EXPLANATORY NOTES – Dam conditions:**

Note: Conditions W41 and W42 to be removed if already conditioned in the authority.

---

**W41** The hazard category of each dam must be determined by a suitably qualified and experienced person at least once in each two year period.

**W42** Dams having a hazard category determined to be significant or high, must be specifically authorised by an environmental authority.

### **Fitzroy River Basin Study**

**W43** The administering authority and the holder of this environmental authority both acknowledge that the conditions for release of contaminants to the XX River in this environmental authority have been calculated without the benefit of the findings of projects proposed to be undertaken as per recommendations 2 and 3 of the *Study of cumulative impacts on water quality of mining activities in the Fitzroy River Basin* (April 2009). The administering authority may, based on the information provided in the study report when it becomes available, all relevant information available at the time and the regulatory framework applicable at that time, consult with the holder of this environmental authority about the conditions in the environmental authority concerning the treatment and disposal of waste water.

The aim of the consultation shall be the meaningful review of the contaminant release limits imposed in this authority having regard to:

- a) the study results;
- b) near field monitoring results;
- c) QLD Water Quality Guidelines; and
- d) best practice environmental management.

If this review leads to a change in the requirements on this environmental authority holder, this shall be advanced by way of an authority amendment or a Transitional Environmental Program and as is necessary or desirable.

**Definitions:**

**"20th percentile flow"** means the 20th percentile of all daily flow measurements (or estimations) of daily flow over a 10 year period for a particular site. The 20th percentile calculation should only include days where flow has been measured (or estimated), i.e. not dry weather days.

**"acid rock drainage"** means any contaminated discharge emanating from a mining activity formed through a series of chemical and biological reactions, when geological strata is disturbed and exposed to oxygen and moisture as a result of mining activity.

**"administering authority"** means the Department of Environment and Resource Management or its successor.

**"appropriately qualified person"** means a person who has professional qualifications, training, skills or experience relevant to the nominated subject matter and can give authoritative assessment, advice and analysis on performance relative to the subject matter using the relevant protocols, standards, methods or literature.

**"dam"** means a land-based structure or a void that is designed to contain, divert or control flowable substances, and includes any substances that are thereby contained, diverted or controlled by that land-based structure or void and associated works. However; a dam does *not* mean a fabricated or manufactured tank or container designed to a recognised standard, *nor* does a dam mean a land-based structure where that structure is designed to an Australian Standard. In case there is any doubt, a levee (dyke or bund) is a dam, but (for example) a bund designed for spill containment to AS1940 is *not* a dam.

**"environmental authority"** means an environmental authority granted in relation to an environmentally relevant activity under the *Environmental Protection Act 1994*.

**"environmental authority holder"** means the holder of this environmental authority.

**"flowable substance"** means matter or a mixture of materials which can flow under any conditions potentially affecting that substance. Constituents of a flowable substance can include water, other liquids fluids or solids, or a mixture that includes water and any other liquids fluids or solids either in solution or suspension.

**"hazard"** in relation to a dam as defined, means the potential for environmental harm resulting from the collapse or failure of the dam to perform its primary purpose of containing, diverting or controlling flowable substances.

**"hazard category"** means a category, either low significant or high, into which a dam is assessed as a result of the application of tables and other criteria in the Manual for Assessing Hazard Categories and Hydraulic Performance of Dams (Version 2.0, 2009) published by the Environmental Protection Agency on its website.

**"natural flow"** means the flow of water through waters caused by nature.

**"receiving environment"** means all groundwater, surface water, land, and sediments that are not disturbed areas authorised by this environmental authority.

**"receiving waters"** means all groundwater and surface water that are not disturbed areas authorised by this environmental authority.

**"representative"** means a sample set which covers the variance in monitoring or other data either due to natural changes or operational phases of the mining activities.

**"saline drainage"** The movement of waters, contaminated with salt(s), as a result of the mining activity.

**"waters"** includes river, stream, lake, lagoon, pond, swamp, wetland, unconfined surface water, unconfined water natural or artificial watercourse, bed and bank of any waters, dams, non-tidal or tidal waters (including the sea), stormwater channel, stormwater drain, and groundwater and any part thereof.

## **Acknowledgements**

I am most grateful for the excellent cooperation and speedy responses to my many questions and requests from all involved in this review. My particular thanks to DNRW Rockhampton (Ed Donohue and his team) and Ensham Resources (Colin Moffett) for their assistance.

Also I am most grateful to Graeme Milligan and Ed Donohue (DNRW), Lindsay Delzoppo (EPA) and Alex Beavers (Premiers) for their assistance as my 'Steering Committee'.

## Headline Findings

1. The decision by the EPA to issue Ensham with a Transitional Environmental Program (TEP) that permitted the discharge of a very large quantity of mine-affected water into the Nogoia-Mackenzie-Fitzroy River system over 7 months (February to September) in 2008 was justifiable.
2. However, this discharge has resulted in:
  - discomfort to the residents of Tieri, Blackwater, Bluff, Middlemount and Dysart due to the poor drinking water quality, but no serious health effects (short or long term),
  - potential discomfort to the residents of Rockhampton due to poor drinking water quality if the system is not flushed this wet season,
  - unquantified effects on the riverine biota, and a high likelihood that there will be serious adverse effects on the spawning success of Fitzroy Golden Perch when the poor quality water (high salinity) is flushed out of the river during the early part of the wet season, exactly the time when this species spawns,
  - no serious short or long term problems for agriculture (irrigation, stock watering),
  - Stanwell Power Station needing to make a range of plant modifications and gain an EPA-approved TEP relating to management of its water discharges.
3. The review has identified issues with the EPA's processes for developing the discharge licence (TEP) to Ensham, particularly limited involvement of key stakeholders, a lack of transparency, and poor communications with key stakeholders and the community during the response to this issue.
4. In the longer term there is a need to strengthen EPA's processes for establishing Environmental Authorities and Transitional Environmental Program (TEP) under the Environmental Protection Act 1994.
5. A number of management actions have been identified that should be implemented immediately to reduce the severity of the drinking water quality problems being experienced by residents Tieri, Blackwater, Bluff, Middlemount and Dysart. But flushing of the mine-affected water from system will only occur during the coming wet season.
6. The available management options are all severely constrained by the current Fitzroy Water Resource Plan (and operational rules), which has virtually all the water in Fairbairn Dam allocated to consumptive uses and no contingency allocation owned by the State. These and other anomalies should be addressed during the 10-yearly review of this plan currently underway.
7. The review identified an urgent need for Government to appoint a 'lead agency' to be the responsible 'caretaker' of river health in the Fitzroy catchment, and for this agency to develop a 'catchment management plan' and a coordinated monitoring and assessment program for the Fitzroy catchment.
8. Government needs to develop a set of Emergency Response Principles relevant to the mining industry to be applied in future situations, such as the current Ensham emergency. These principles would include the need to: identify a lead agency, undertake a risk assessment, coordinate key agencies, develop an action plan, develop a communications plan, and identify a key spokesperson.

## Executive Summary

This report contains a review of the current situation regarding water quality in the Fitzroy River resulting from the discharge of 138 Gigalitres of mine-affected floodwater from the Ensham Resources Pty Ltd (Ensham) coal mine located near Emerald in Central Queensland.

The Terms of Reference (ToR) for this review are to advise the Queensland Premier on:

- any short and long-term risks to human health, aquatic ecology, agriculture and industry that could result from the mine-affected floodwaters discharged from the Ensham coal mine, and how these should be managed,
- the scope of the water quality and biological monitoring program to be undertaken by the EPA to assess the potential impacts of the mine-affected floodwater discharge from Ensham coal mine,
- any changes that might be made to conditions of Environmental Authorities (for mining activities) and associated statutory documents under the *Environmental Protection Act 1994* in order to ensure that the impacts of discharges of mine-affected waters in Central Queensland are appropriately managed and monitored,
- any other matters that might be of relevance to this issue.

This review has focused on the risks from the mine-affected water discharge from Ensham. It is recognised that there are a number of other issues relating to coal mining in the Fitzroy Catchment that are of concern to community groups, but these are not covered in this Report.

The main conclusions and recommendations of this review are listed below.

### **Risks to human health, aquatic ecology, agriculture and industry**

#### ***Human health***

##### Blackwater, Bluff, Tieri, Middlemount and Dysart

There is no evidence of any serious health problems in the above townships due to the elevated sodium levels in their drinking water supply. However, it is possible that the poor quality water did increase the effects of a viral gastroenteritis outbreak in the region in late August 2008.

There is considerable evidence that the residents have been adversely affected by the poor taste of their drinking water supply.

Additional major concerns are that: (a) downstream drinking water supplies appear not to have been considered by the EPA in issuing the TEP, (b) neither the Central Highlands Regional Council, Queensland Health nor the residents were informed of the impending problems early enough, and (c) media reports indicate significant community concern about this issue, a lack of trust in Government to fix the issue, and resentment with Ensham.

##### Rockhampton

It seems unlikely that any serious health problems will arise as a result of the current (October 2008) increased salinity and sodium concentrations in Rockhampton's drinking water supply. These concentrations are likely to increase further during November (and even December if there is a lack of rain), but provided medical practitioners and the small number of vulnerable people are well informed, and there is access to bottle water, serious health problems are unlikely to occur.

It is quite possible that Rockhampton Regional Council will experience a large increase in complaints about the poor taste of the drinking water, at least until the Fitzroy Barrage is fully flushed.

If Rockhampton's water supply decreases further in quality, problems are also expected at the Rockhampton Hospital and its Dialysis Clinics and Home Dialysis service.

There is a real possibility that blue-green algal blooms will occur in the Fitzroy Barrage in the next month or so, given that water in the Barrage is considerably clearer than normal. However, the Rockhampton Regional Council are aware of this possibility and have contingency measures in place to minimise any risks to human health from blue-green algal toxins in drinking water supplies.

Additional concerns are that: (a) downstream drinking water supplies for the major population centre of Rockhampton appear not to have been considered by the EPA in issuing the TEP, (b) neither the Rockhampton Regional Council, Queensland Health nor the residents were informed of the situation early enough, and (c) media reports indicate significant community concern about this issue, a lack of trust in Government to fix the issue, and resentment with Ensham.

### ***Aquatic biota***

Review of the possible effects on river health has been hampered by a dearth of relevant information.

It is clear that there have not been any catastrophic effects (e.g. major fish kills) on the fish population in the Nogoia-Mackenzie-Fitzroy River system during the time the Ensham mine-affected discharge occurred. This is consistent with the available evidence suggesting that most Australian adult fish species are relatively tolerant of increased salinity, and unlikely to be adversely affected by salinities up to around 1,500  $\mu\text{S}/\text{cm}$ .

However, this is not true for the effects of increased salinity on the early life stages of fish (e.g. survival of eggs and larvae), where the small amount of available evidence suggests that salinities of 1,000-1,500  $\mu\text{S}/\text{cm}$  are likely to cause adverse effects.

It seems quite possible that this coming wet season could result in serious adverse effects on the spawning success of Fitzroy Golden Perch because of the poor quality water (high salinity) that will be flushed out of the river during the early part of the wet season, exactly the time when this species spawns.

The results of a study by Biosecurity Queensland indicated that catfish sampled from Bedford and Tartru Weirs were in poor health. However, it was not possible to relate these back to the mine-affected water discharged to the river system.

There is no evidence of adverse effects on the aquatic biota due to heavy metals in the mine-affected water.

The available information on the sensitivity of macroinvertebrates to increased salinity levels suggests that adverse effects are unlikely to occur at levels below around 1,000  $\text{mS}/\text{cm}$ . However, this level is based on data that mostly relate to short-term studies, and not to continual exposure over a 7-8 month period. Advice has been obtained suggesting that a rapid rise in salinity to levels of 1,000-1,500  $\mu\text{S}/\text{cm}$  would adversely affect macroinvertebrate communities (particularly mayflies), given the quite low salinity (200-300  $\mu\text{S}/\text{cm}$ ) they normally experience.

There is insufficient information available to make an assessment of potential adverse effect on other biota, such as frogs, platypus and turtles.

Again there is insufficient information available to assess whether the increased clarity of the water in the river system as a result of the mine-affected discharge, has resulted in major changes to the aquatic ecology, including increased algal production, increased predation and changes to important food webs (i.e. what eats what).

The response of relevant Government agencies to assessing the possible impacts of the mine-affected water on the riverine biota has been tardy to say the least. The EPA is currently (November 2008) coordinating a comprehensive monitoring and assessment program (water quality, sediments and biota) to determine if there have been adverse effects in the Fitzroy River system due to the mine-affected water.

### ***Agriculture***

It is unlikely that the Ensham mine-affected water has or will caused any major problems for agriculture.

### ***Industry***

#### Coal industry

The coal industry is the major industrial user of water in the Fitzroy catchment. Water is used for coal processing, dust suppression, in underground operations and in industrial areas. It is unlikely that water with conductivities to around 1,500  $\text{uS}/\text{cm}$  would cause any major problems to the coal industry. However, there is evidence that an increase in raw water salinity can lead to increased maintenance costs.

#### Stanwell Power Station

The mine-affected water has had no impact on electricity generation activities to date. Additionally, Stanwell Power Station expects to be able to handle likely salinity increases in their raw water over the next month or so, and do not expect any impact on electricity generation.

### **Options available to manage these risks**

A number of sensible and feasible management options have been identified by the Technical Working Group (TWG) to address the current water quality problems in the Nogoia-Mackenzie-Fitzroy system. If implemented these management actions will have some positive effect on both

drinking water quality and river health, and will show to the community that Government is serious about this issue and prepared to do something positive about it.

However, the ultimate flushing of the mine-affected water currently in the Fitzroy system will only occur with the large flows normally expected in the wet season (December-March).

It should be noted that all the management options currently being considered to alleviate the current water quality problems are restricted to a very large extent by the water use rules (ROP) for the Nogoa-Mackenzie River system, rules that appear to be largely dictated by agricultural and industrial use of the water. These rules may need to be modified in the future to consider other legitimate users of water, such as the environment and townships, and the possible need for a State-owned contingency licence to a certain proportion of the water in Fairbairn Dam.

Option A (to address some of the issues in Bedford and Bingeang Weirs) should be implemented as soon as possible, given the time (approx. 3 weeks) for water to get from Fairbairn Dam to dilute that in Bedford Weir. Implementation of this Option would have community support in that the Government would be seen to be doing something positive.

Further, it is recommended that the Central Highland Regional Council establish a Task Force to develop a contingency plan for addressing the drinking water quality issue for Blackwater, Bluff, Tieri, Middlemount and Dysart should the Bedford and Bingeang Weirs not be adequately flushed during this coming wet season.

Option C (to address water quality issues in Eden Bann Weir and the Fitzroy Barrage) should be implemented as soon as possible.

Additionally, a contingency plan should be developed by DNRW during November to handle the possibilities that: (a) additional mine-affected water will be flushed into this system from the Isaac/Connors system, and (b) that the expected normal wet season flows will not occur and the dilution and flushing of mine-affected water from Eden Bann Weir and the Fitzroy Barrage does not occur.

An emergency water management plan should be developed by DNRW during November 2008 to improve water quality in the Nogoa-Mackenzie-Fitzroy River system between the storages. This plan will need to be innovative and not constrained by the current restrictive ROP rules.

#### **Review of the EPA-coordinated monitoring & assessment program**

The response of relevant Government agencies to assessing the possible impacts of the mine-affected water on the riverine biota has been tardy, so much so that the Premier, in October 2008, directed the EPA to establish a whole-of-government monitoring program to assess the potential impacts of mine-affected floodwater discharged from the Ensham mine on the Nogoa-Mackenzie-Fitzroy River system.

A draft Project Plan (Fitzroy Basin Water Quality Monitoring: Assessing the impact of Ensham floodwater release, Version 1.0, 28 October 2008) to undertake a comprehensive study of the water quality, sediments and biota in the system has been developed.

This review provided comments to the EPA (29 October 2008) aimed at strengthening the program. A full assessment of the final monitoring and assessment program will be made in a separate report.

Because there is little baseline information available, this study will be challenged in determining if any short-term biological impacts have occurred due to the mine-affected water. For this reason, the study should continue for at least 2 years (3 wet-dry cycles) so that any recovery in the condition of the biota can be measured. The information on the system that will be collected during this time will also be vital in the development of a more comprehensive Fitzroy catchment-wide monitoring and assessment program.

#### **Assessment of the Government actions to manage the Fitzroy water quality issue**

This current water quality issue in the Nogoa-Mackenzie-Fitzroy River system arose as a result of an emergency situation caused by flooding of the Ensham coal mine in January 2008, the desire by Ensham and Government to get the mine back into production as rapidly as possible, and the decision by the EPA to grant Ensham a Transitional Environmental Program (TEP) to discharge a very large volume (138 GL) of mine-affected water into the Nogoa River.

Given all the factors, the decision by the EPA to issue Ensham with a Transitional Environmental Program for the mine-affected water was justifiable.

However, my assessment is that the EPA process for determining the Ensham TEP was less than adequate (for the reasons outlined in Section 3.4), and that EPA did not adequately consult with

key stakeholders in establishing the TEP, or inform the community generally about what was happening and what the possible effects could be. The whole process lacked transparency.

My assessment is that the EPA underestimated the scale of this emergency situation (discharge of a very large volume (138 GL) of mine-affected water over a period of 6-8 months to a river system that was largely not flowing), and as a result misjudged the community reaction to what was happening.

### ***Adequacy of the current Government actions***

Government actions since late August have been mixed in their responsiveness and effect. These are summarized in the main report.

The somewhat cynical community view of the current Government response to this issue is: (a) that the establishment of the TWG and my review are welcome initiatives but they will be too late to result in any management actions to solve the immediate problem, (b) that the Government is waiting for the wet season rains to 'solve' the problem, and (c) that nothing will be learned from this issue to change Government response processes.

While it is true that flushing of the mine-affected water currently in the Fitzroy system will really only occur with the large flows normally expected in the wet season (December-March), the management actions recommended in Section 5 of this report will have some positive effect on both drinking water quality and river health. If initiated, these management actions will show to the community that Government is serious about this issue and prepared to do something positive about it.

The establishment of the Fitzroy River Water Quality Technical Working Group (TWG) in September 2008 has been a very positive move. The TWG has significantly improved the level of knowledge and data sharing, and has provided a forum for sensible discussion about possible management actions.

The EPA-coordinated monitoring and assessment program is also a welcome initiative. However, as noted in the report this would not have been needed if adequate monitoring had been required as part of the Ensham TEP. Also, it is disappointing that it has taken until November for this to have been established when the issue was well appreciated as long ago as late August.

### ***Change needed to manage the Fitzroy water quality situation going forward?***

There appears to be little more the Government can do about this current water quality issue, assuming that decisions are made quickly to initiate the recommended management actions. However, this water quality issue has highlighted a number of broader issues that need to be addressed in the longer term.

#### TEP process

The most obvious is the deficiencies in the TEP process (lack of adequate consultations between the EPA and key stakeholders, lack of transparency in the process, poor communication with the key agencies and the community about the reality of the water quality issue and what could be done about it). Largely because of the poor communications, but also because of the lack of credible monitoring information, a range of 'conspiracy' theories arose and escalated the issue.

A review of the EPA procedures for developing TEPs has been recommended, with the results (a new set of guidelines) to be published on the EPA web site.

#### Monitoring and assessment

There are a number of monitoring programs being undertaken in the Fitzroy Basin (TWG Document), but it is clear they are largely focused on the specific responsibilities of particular agencies, are not well coordinated, and are not comprehensive.

This review has identified an urgent need for the establishment of comprehensive and well coordinated long-term monitoring and assessment program to assess the ecological health of the Fitzroy River system.

#### Fitzroy Water Resources Plan

The available options to manage this water quality issue are all severely constrained by the current Fitzroy Water Resource Plan (and operational rules), which has virtually all the water in Fairbairn Dam allocated to consumptive uses, and no contingency allocation owned by the State.

DNRW should consider a more equitable balancing of water between consumptive users and the environment, and the provision of State-owned contingency allocation, during the 10-yearly review of the Fitzroy Water Resource Plan that is currently underway and scheduled to be completed in late 2009.

### Caretaker of river health

Another important issue that has been highlighted by the current water quality issue is there is no well-defined 'caretaker' of river health in the Fitzroy River catchment, with the legislative authority to adequately protect the aquatic environment. The EPA, DNRW and the Fitzroy Basin Association all appear to have some responsibilities in this regard.

Government should consider the appointment of a 'lead agency' to be the responsible 'caretaker' of river health in the Fitzroy catchment, and for this agency to develop a 'catchment management plan', and a coordinated catchment-wide monitoring and assessment program.

### Emergency response

It is clear that the Government processes for addressing the current Ensham emergency could be improved. Given the climate change predictions of greater variability in climate over the next 30-50 years, it is certain that similar emergency situations will occur sometime in the future.

Government should develop a set of Emergency Response Principles relevant to the mining industry to be applied in future situations, such as the current Ensham emergency. The Emergency Response Principles should include the need to: identify a lead agency, undertake a risk assessment, coordinate key agencies, develop an action plan, develop a community communications plan, and identify a key spokesperson.

## **Recommendations**

### Transitional Environment Program Process

- Rec 1: that EPA undertake a review of the procedures used to develop TEPs and publish the results (a new set of guidelines) on the EPA web site. This review should consider the need for (a) criteria for prioritising the importance of the TEP, (b) undertaking a risk assessment to assist in developing the TEP, (c) a checklist that ensures that all beneficial uses of the receiving waterbody are explicitly considered, (d) a better process for identifying and including key stakeholders in the TEP process, (e) better processes for ensuring the quality of the TEPs developed (e.g. documenting the reasons for various decisions or judgements), and (f) a process for informing the community of the situation associated with potentially controversial TEPs.
- Rec 2: that EPA introduce a process where they undertake random audits of the laboratories being used by mining companies for their ability to adequately sample, process and analyse water quality samples for heavy metals at trace concentrations.

### Monitoring & assessment

- Rec 3: that EPA include the review comments in revising the draft Project Plan (Fitzroy Basin Water Quality Monitoring: Assessing the impact of Ensham floodwater release), and include a longer timeline for the study (at least 2 years - 3 wet-dry cycles) so that any recovery in the condition of the biota can be measured.
- Rec 4: that the EFAP surveys to be undertaken by DNRW this coming wet season are expanded to ensure that the effects of the flushing of higher salinity water on fish (and particularly Fitzroy Golden Perch) spawning and recruitment are measured and the implications for future years published.
- Rec 5: that the Biosecurity Queensland study of the 'health' of the fish in weirs be repeated, with other fish species and other storages included, and the study design improved.

### Management Actions

- Rec 6: that Option A (to address some of the issues in Bedford and Bingegang Weirs) be implemented immediately, given the time for water to get from Fairbairn Dam to dilute that in Bedford Weir (3 weeks).
- Rec 7: that the Central Highland Regional Council establish a Task Force to develop a contingency plan for addressing the drinking water quality issue for Blackwater, Bluff, Tieri, Middlemount and Dysart should the Bedford and Bingegang Weirs not be adequately flushed during this coming wet season.
- Rec 8: that Option C (to address water quality issues in Eden Bann Weir and the Fitzroy Barrage) be implemented immediately.
- Rec 9: that a contingency plan be developed by DNRW during November to handle the possibilities that: (a) additional mine-affected water will be flushed into this system from the Isaac/Connors system, and (b) that the expected normal wet season flows will not

occur and the expected dilution and flushing of mine-affected water from Eden Bann Weir and the Fitzroy Barrage do not occur.

- Rec 10: that an emergency water management plan be developed during November 2008 to improve water quality in the Nogoa-Mackenzie-Fitzroy River system between the storages. This plan will need to be innovative and not constrained by the current restrictive ROP rules.

#### Fitzroy Water Resource Plan

- Rec 11: that DNRW consider a more equitable balancing of water between consumptive users and the environment, and the provision of State-owned contingency allocation, during the 10-yearly review of the Fitzroy Water Resource Plan that is currently underway and scheduled to be completed in late 2009.

#### Caretaker of river health

- Rec 12: that Government consider the appointment of a 'lead agency' to be the responsible 'caretaker' of river health in the Fitzroy catchment, and for this agency to develop a 'catchment management plan', and a coordinated catchment-wide monitoring and assessment program.

#### Emergency response

- Rec 13: that Government develop a set of Emergency Response Principles relevant to the mining industry to be applied in future situations, such as the current Ensham emergency.

## 1. Introduction

This Report contains a review of the current situation regarding water quality in the Fitzroy River resulting from the discharge of 138 Gigalitres (130,000 Megalitres or 138 billion litres) of floodwater from the Ensham Resources Pty Ltd (Ensham) coal mine located near Emerald in Central Queensland.

The terms of reference (ToR) for this review are to advise the Queensland Premier on:

- any short and long-term risks to human health, aquatic ecology, agriculture and industry that could result from the mine-affected floodwaters discharged from the Ensham coal mine, and how these should be managed,
- the scope of the water quality and biological monitoring program to be undertaken by the EPA to assess the potential impacts of the mine-affected floodwater discharge from Ensham coal mine,
- any changes that might be made to conditions of Environmental Authorities (for mining activities) and associated statutory documents under the *Environmental Protection Act 1994* in order to ensure that the impacts of discharges of mine-affected waters in Central Queensland are appropriately managed and monitored,
- any other matters that might be of relevance to this issue.

A visit to the region was made in the period 21-23 October 2008, during which time I inspected the Ensham mine site and travelled the length of the Mackenzie/Fitzroy River from Emerald to Rockhampton, had discussions with the Mayor's of the Central Highlands Regional Council and the Rockhampton Regional Council, and attended a meeting of the Fitzroy River Technical Working Group. Also meetings were held with EPA, DNRW and Ensham Resources in Brisbane on 11 November 2008. Additionally, a large number of reports and monitoring data have been reviewed. These are listed in the Reference section.

There are a number of other issues relating to coal mining in the Fitzroy Catchment that are of concern to community groups. These include the cumulative effect of waste discharges from the large number of mines in this catchment, mining on floodplains, mining under rivers, the effect of discharges of floodwater from mines other than Ensham, particularly those in the Isaac-Connors Catchment, and future controls on flood protection measures at Ensham and other mines on floodplains. These issues are not covered in this report, except to comment on the potential impact of mine-affected water currently in the Isaac-Connors system that will eventually be flushed into the lower Fitzroy River just above Tartrus Weir.

This review has identified seven major issues associated with the current water quality issue in the Fitzroy River system:

- the current risks to human health (drinking water), aquatic ecosystems, agriculture and industry as a result of the mine-affected water discharge that has now been in the Nogo-Mackenzie-Fitzroy River system for over 8 months (Section 4 of this report),
- the options available to manage these risks (Section 5),
- the conditions and decision-making processes associated with the discharge license (Transitional Environmental Program - TEP) issued to Ensham by the EPA (Section 3.4),

- the lack of adequate communication about the discharge and its possible consequences to key stakeholders and the community (Section 7),
- the lack of adequate monitoring (particularly biological) of the impacts of the mine-affected water in the system – a new monitoring program being coordinated by the EPA is addressed in Section 6 of this report,
- the lack of a ‘caretaker’ of river health and a ‘catchment management plan’ to guide the TEP process (Section 7),
- Government response to this emergency situation, and arrangements that need to be put in place to ensure that future emergencies in the mining industry are better handled (Section 7).

## 2. Background

Significant rainfall fell over much of the Bowen Basin area of Central Queensland in January 2008, resulted in major local flooding (BoM, 2008). In particular, the regional towns of Emerald, Moranbah and Mackay were flooded, as were a number of coal mines in the region.

The focus of this report is the Ensham coal mine, an open cut thermal mine located approximately 35 km east of Emerald, which was inundated by floodwaters from the Nogoia River when a levee bank overtopped and then failed on the 19 January 2008. A total of approximately 150 GL of floodwater entered the mine pits during this flood.

Ensham produces 8 - 9 million tonnes of coal per annum for the domestic and export Thermal Coal markets. The company is also responsible for the direct and in-direct employment of over 3,000 people in the Central Queensland Region, providing a significant annual contribution to the local, regional and Queensland State economy through employment and support services, royalties and use of numerous services.

Following the flooding events of January 2008, Ensham sought the necessary approvals required to remove the estimated 150,000 ML of mine-affected floodwater and to secure on-going flood protection for the mining operation in order to: protect the safety of the mine and its employees from further flooding, recover Ensham's capacity to supply customers and restore its economic contribution to Central Queensland, and to safeguard over 3,000 Queensland jobs.

The Environmental Protection Agency (EPA) provided authority for the discharge of the mine-affected floodwater through the issuance of a Transitional Environmental Program (TEP) under the *Environmental Protection Act 1994*. The TEP is covered more fully in Section 3.3.

It should also be noted that a number of other coal mines were flooded during January 2008, and discharged various volumes of mine-affected water into tributaries of the Fitzroy River system under TEP's or existing Environmental Authorities (EA) issued by the EPA.

Ensham discharged 138 GL of mine-affected floodwaters into the Nogoia-Mackenzie-Fitzroy River system over a 7-month period (February to September 2008). Details of the quality and quantity of the discharged water are provided in Section 3.2, and an assessment of the impacts of this mine-affected floodwater on downstream uses (drinking water, aquatic ecosystem, agriculture, industry) is contained in Section 4.

There has been intense community and media interest in the impacts of the mine-affected water in the Nogoa-Meckenzie-Fitzroy system, commencing around August 2008. The major concerns include:

- Health effect from the elevated sodium levels in drinking water supplied to Blackwater, Bluff and Tieri,
- The poor taste of drinking water supplied to Blackwater, Bluff and Tieri,
- Possible taste and health effects in Rockhampton's drinking water supply,
- Livestock refusing to drink water taken from the river,
- Disruption to Stanwell Power Station's operations due to higher salinity cooling water,
- Adverse effects on the aquatic biota, including fish, macroinvertebrates and turtles,
- The lack of information provided by authorities to the community,
- The EPA's processes in issuing a discharge licence to Ensham.

### **3. Current situation**

#### ***3.1 The Fitzroy River system***

The Fitzroy River catchment stretches from the Carnarvon Gorge National Park in the West to Rockhampton on the central Queensland coast, encompassing a largely sub-tropical and semi-arid region of Australia (Figure 1). The Fitzroy catchment, at nearly 150,000 km<sup>2</sup> in area, is the second largest in Australia after the Murray-Darling system.

Agriculture is the major land use in the catchment, with grazing the dominant use (90%) and smaller area of irrigated cotton and horticulture, dryland cropping, forestry, mining and conservation (Christensen and Rogers, 2006). Mining is dominated by coal (production 100 million tonnes/year), magnesite, nickel and historically gold and silver.

Rainfall occurs predominantly in the summer (December – March) and varies from around 800 mm/y at Rockhampton near the coast to around 516 mm/y at Emerald further inland. As a result most of the mean annual discharge of about 5,000 GL in the Fitzroy River occurs in the summer wet season. There are several large sub-catchments, including the Comet, Nogoa, MacKenzie, Connors, Isaac and Dawson contribute flows to the Fitzroy. Many of the streams in the Fitzroy catchment are ephemeral and only flow during the wet season.

The coal-rich Bowen Basin underlays a considerable proportion of the Fitzroy catchment. In total there are 37 existing coal mines in the catchment with a further 17 new mines proposed.

The major rivers that make up the Fitzroy River system include the Nogoa, Mackenzie, Dawson, Isaacs and Connors Rivers (see Figure 1).

This report focuses on the Nogoa-Mackenzie-Fitzroy Rivers, the part of the system affected by the Ensham discharge<sup>1</sup>. This stretch of the river is highly

---

<sup>1</sup> As well as discharge of flood waters from other mining operations into the tributaries of the Fitzroy River, following those same flood events, and in February and March overland flows that occurred during the flood events of early 2008.

regulated, with one major reservoir (Fairbairn), four weirs (Bedford, Bingegang, Tarrus, Eden Bann) and a large Barrage (at Rockhampton) all built on the river (see Figure 2 for a schematic diagram of the system). These reservoirs and weirs can hold a total of 1,660 GL when at full supply level, with Fairbairn Dam by far the largest holding around 90% of the total (Data from DNRW Rockhampton).

Figure 1: Map of the Fitzroy catchment showing the Ensham mine, major towns, major river systems, reservoirs and weirs, and roads

Flow in the Fitzroy River is very seasonal, with most of the flow occurring during the wet season from December to March. Figure 3 shows the monthly mean and median flows in the Fitzroy River at Riverslea. Comparison of these data shows that, while the general picture is of most flow during the wet, this can vary significantly

depending upon the particular year. Additionally, large flows can also occur at other times of the year.

Interestingly, the total storage (1,660 GL) in the Nogoia-Mackenzie-Fitzroy system is close to the total median annual flow (1,151 GL) and about one third the total mean annual flow (4,737 GL) in the system. However, maximum annual flows in this system are over an order of magnitude greater than the mean annual flow.

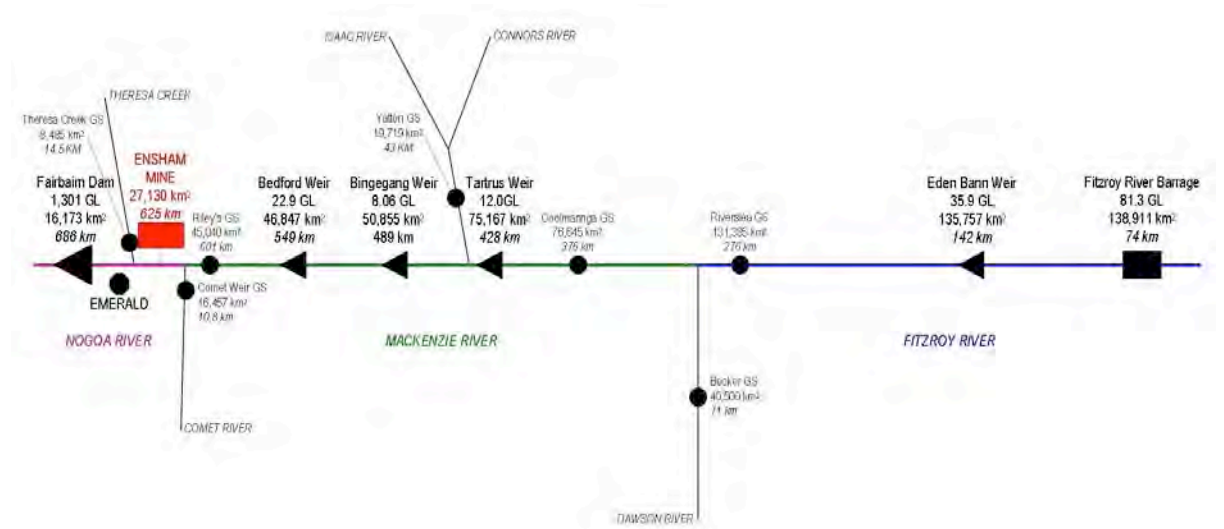

Figure 2: Schematic of the Nogoia-Mackenzie-Fitzroy river system, showing the location and full supply level volume of all weirs and reservoirs

Figure 3: Long term mean and median monthly flows (Gigalitre – GL) in the Fitzroy River at Riverslea

### 3.2 Quality of the mine-affected water

A total of 138 GL of mine-affected water was discharged to the Nogoia River from the flooded pits over a period of around 7 months (Table 1). The floodwater was in the pits for around 16 days before discharge commenced from Pit B on 3 February 2008,

and during this time (and subsequently) it dissolved a quantity of salts, largely from the overburden<sup>2</sup>. Little of the coal seam was exposed to the floodwaters, a fact that is important regarding the quality of the mine-affected water eventually discharged.

Ensham have monitored the quality of the pit water since the flooding occurred. Table 2 provides a summary of the changes in quality over the period 11 June to 11 September 2008 for Pit B and Pits C & D. Figure 4 provides a map of the Ensham mine site showing the location of the pits, discharge points and monitoring sites.

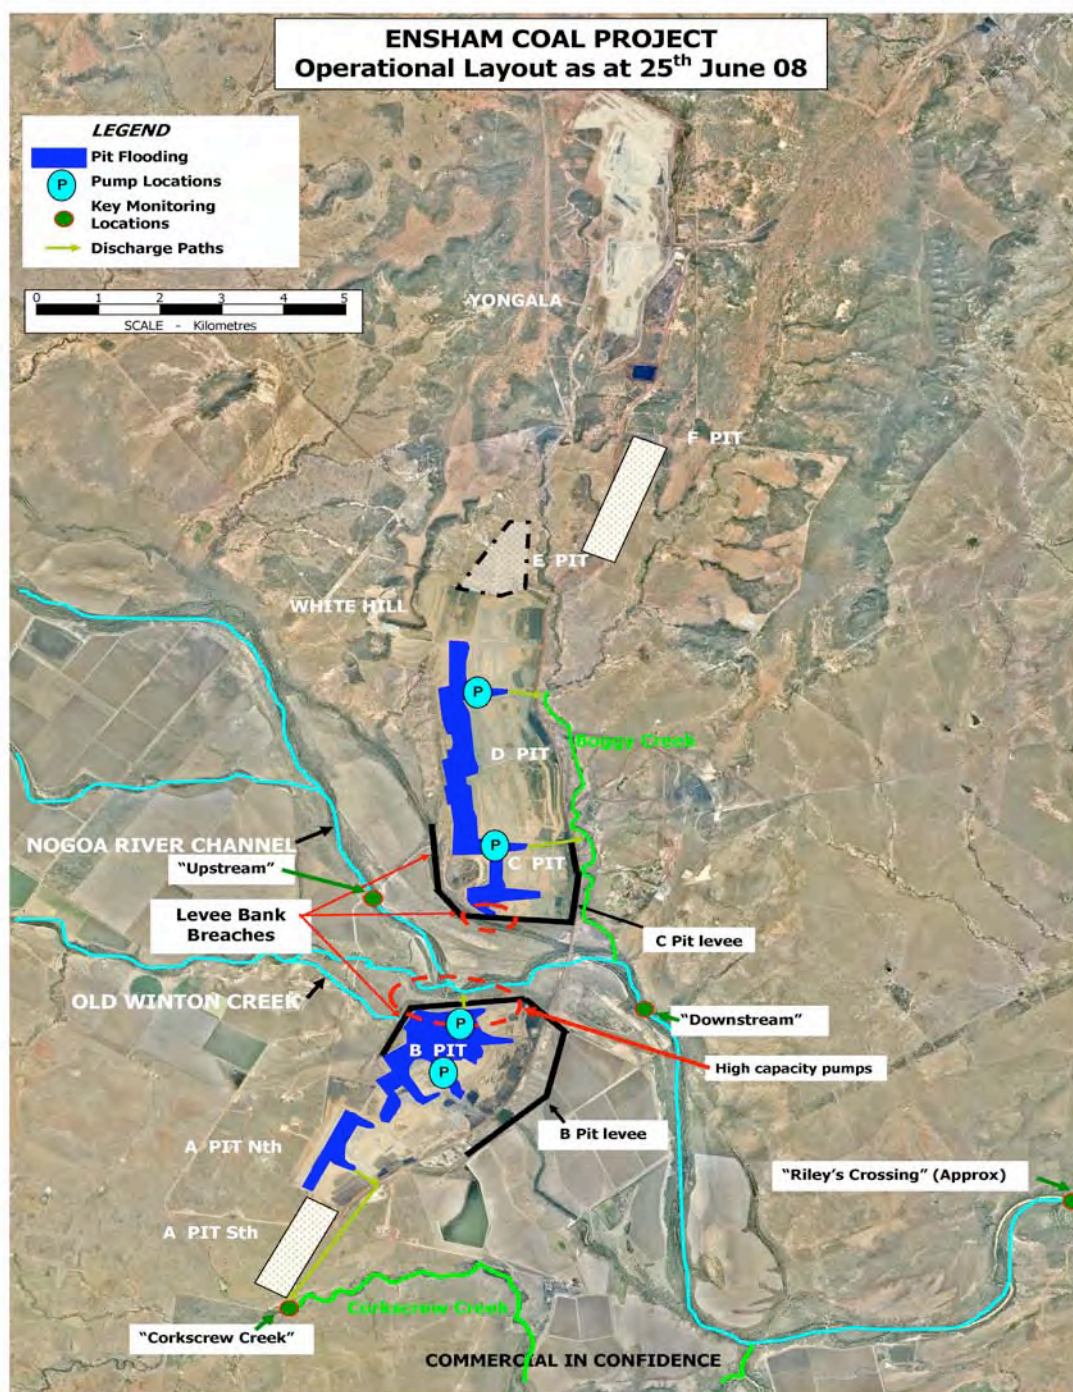

Figure 4: Map of the Ensham mine site showing the location of the pits, discharge points and monitoring sites

<sup>2</sup> The overburden consists mainly of sandstones and siltstones.

The composition of the dissolved salts is largely sodium chloride (ca. 60%), with smaller amounts of sodium, calcium and magnesium sulfates and bicarbonates, and low concentrations of heavy metals (Table 2). It is also important to note that the high pH (around 8), relatively low sulfate concentration and low heavy metal concentrations are evidence that acid mine drainage, often associated with coal and base metal mines, was not a major issue at Ensham.

A limited review<sup>3</sup> of the sampling, treatment and analysis of water samples for heavy metals was undertaken. This revealed a number of issues with the procedures used for filterable or dissolved heavy metals (e.g. samples not filtered and acidified in the field, but in the laboratory; filters were not acid washed; analytical result for ultrapure water and acid blanks not provided; calibration curves appear to be inappropriate for trace level analysis; quality assurance results not reported), so that all filterable metal concentrations must be treated as questionable.

The EPA adequately specified in the TEP(s) issued to Ensham that sampling, processing and analysis should follow procedures outlined in the Queensland EPA Water Quality Sampling and Monitoring Manual, and that the samples should be taken by an appropriately trained person. Equally, Ensham engaged consultants that had the required accreditation (e.g. NATA accredited laboratories) to do this work. However, despite all this it appears that some essential procedures were not followed.

*It is recommended that EPA introduce a process where they undertake random audits of the laboratories being used by mining companies for their ability to adequately sample, process and analyse water quality samples for filterable (dissolved) heavy metals at trace concentrations.*

The mine-affected pit water was discharged into the Nogoia River over a 7-month period, when the river flow was very low, and there was limited capacity for dilution to occur. Figure 5 is a graph of the flow in the Nogoia River over the period January 2008 to October 2008, measured at Riley's Crossing downstream of the mine. The discharge from Ensham is also shown (in red), and obviously makes up most of the river flow during the period April to early September 2008<sup>4</sup>.

Table 1: Volumes of mine-affected water discharged from the Ensham mine

<b>Location</b>	<b>Duration of discharge (2008)</b>	<b>Total volume discharged (GL)</b>
Pit A	7 June – 9 September	8.7
Pit B	3 February – 2 September	58.1
Pits C & D	2 May – 9 September	71.4
<b>Total</b>	<b>3 February – 9 September</b>	<b>138.3</b>

<sup>3</sup> Through Ensham I asked a series of questions of the laboratory to ascertain the procedures used.

<sup>4</sup> The discrepancy between the volume pumped from the flooded mine and the actual flow probably represents extraction of water from the river by downstream farmers.

Figure 5: Flow (ML/day) in the Nogoia River over the period January 2008 to October 2008, with the discharge from Ensham also shown (in red)

\* Pit B, Ramp 24; \*\* Pits C&D, Ramp 6, \*\*\* Total (unfiltered) heavy metal concentrations reported. The analytical methods used to obtain the filterable (dissolved) heavy metal concentrations are questionable (see text).

To ensure that water discharge approval specifications were met, Ensham purchased sufficient 'Seasonal Water Allocation' from water allocation holders, to dilute the floodwater discharged from the mine. The appropriate dilution of the floodwater discharge was then obtained by controlling the daily release rate of the 69.3 ML of purchased water, with the pumping rate of the mine floodwater discharge. This Fairbairn Dam water was released over the period 19 June to 8 September 2008. Twice daily sampling at the Ensham 'Upstream' and 'Downstream' monitoring points was used to provide control, monitoring and reporting of this process.

In terms of loads of salt added to the River system, I have estimated that the entire release from Ensham contributed around 100,000 tonne of salt to the system<sup>5</sup>. This compares with a load of around 184,000 tonne<sup>6</sup> transported in an average year by the Nogoa River and 850,000 tonne<sup>7</sup> transported by the Fitzroy system. Thus, the discharged load from the mine represented an additional 55% over that transported annually by the Nogoa River. However, this statistic under-represents the magnitude of the actual change in the Nogoa River during 2008, since the discharge occurred during the dry season when there was little natural flow (and hence little salt transport) in this river.

### **3.3 Quality of the river water**

Table 3 provides a summary of the water quality in the Nogoa-Mackenzie-Fitzroy system over the period July to October 2008, as illustrated by the quality of water in Bedford and Tarrus Weirs. These data were supplied by Ensham.

As expected, the conductivity and major ions are all elevated, the turbidity is low (water clear) and the pH is elevated (possibly because of high algal productivity). The heavy metal concentrations are all very low and all (except aluminium) are below the ANZECC (2000) trigger levels for 95% ecosystem protection.

Monitoring of the conductivity (salinity) in the river system over the discharge period shows that the mine-affected water is moving very slowly through the system as a 'slug' of poor quality water of around 400 km in length. Figure 7 shows the progress of the mine-affected water through the Nogoa-Mackenzie-Fitzroy system between June and October 2008. The downstream extent of the slug is currently (end of October 2008) the Rockhampton Barrage.

It is significant that the volume of mine-affected water discharged from the Ensham mine (138 GL) is almost the same as the volume of water (117 GL) estimated to be present in the Nogoa-Mackenzie-Fitzroy system during the dry season (Data from DNRW Rockhampton)<sup>8</sup>.

<sup>5</sup> Assume average concentration 720 mg/L (1,200 uS/cm) and a volume of 138 GL.

<sup>6</sup> Assume average concentration 180 mg/L (300 uS/cm) and an annual average volume of 1020 GL at Riley's Crossing.

<sup>7</sup> Assume average concentration 180 mg/L (300 uS/cm) and an annual average volume of 4,700 GL at Riverslea.

<sup>8</sup> Assumes all weirs and Barrage are at full supply level.

### 3.4 Discharge licence (Transitional Environmental Program – TEP)

The EPA has issued five approvals to Ensham to permit the discharge of floodwater from the mine. These include:

- Emergency direction to discharge from mining pits B, C and D on ML7459 Ensham coal mine, 1 February 2009.
- Emergency direction to discharge from mining pits B, C and D on ML7459 Ensham coal mine, 15 February 2009.
- Draft Transitional Environmental Program for pit dewatering at ML7459, TEP Certificate of Approval number EMD 001-08, 6 March 2008<sup>9</sup>.
- Transitional Environmental Program - Amended Certificate of Approval number EMD 001-08, 28 April 2008.

<sup>9</sup> This TEP was issued in response to a submission from Ensham (29 February 2008) for a TEP to permit dewatering of the flooded Ensham mine.

- Transitional Environmental Program - Amended Certificate of Approval number EMD 001-08, 2 June 2008.

The TEP Certificates of Approval were modified over time, presumably as a result of operational difficulties faced by Ensham in discharging such a large quantity of mine-affected water.

The Certificates of Approval specify (a) where the discharges can occur, (b) that the volumes released must not cause downstream flooding, (c) that physical damage to the rivers must be minimised, (d) the water quality monitoring (parameters, frequency, locations) that must be undertaken, and (e) the conditions under which the discharge must cease<sup>10</sup>.

My assessment is that the EPA process for determining the Ensham TEP was less than adequate for the following reasons:

- There was no written assessment of the risks to the downstream water users, including aquatic ecosystems, town drinking water or industry, before the TEPs were issued<sup>11</sup>.
- Inadequate account was taken of the impact of the mine-affected water upon any downstream values (apart from agriculture), despite the obvious fact that a very large volume of mine-affected water was to be discharged to the river system largely during the time (dry season) when there would be very low flows and limited dilution or flushing<sup>12</sup>,
- The monitoring required of Ensham was inadequate.
  - Until the 2 June TEP monitoring was limited to surface water quality and only extended to a monitoring site in the Nogoia River just downstream of the mine lease boundary<sup>13</sup>,
  - In the 2 June TEP, Ensham were also required to monitor surface water quality at Riley's Crossing on the Nogoia River<sup>14</sup>,
  - I find it surprising that Ensham were not required to monitor conductivity continuously, particularly at the downstream sites<sup>15</sup>,

---

<sup>10</sup> The latest TEP (2 June 2008) requires that discharge must cease if the rolling median value for the most recent five weeks (of weekly) water monitoring data at compliance points 2 (Nogoia River), 3 (Corkscrew Creek) and 4 (Riley's Crossing) exceed specified limits.

<sup>11</sup> Ensham did obtain advice in June 2008 on possible environmental impacts from the discharged flood water (4T Consultants, 2008), but it appears that this information was not provided to the EPA.

<sup>12</sup> The TEP issued on 6 March 2008 contained Condition 7 that aimed to limit heavy metal concentrations such that aquatic life was protected. However, this was removed in the TEP issued on 28 April 2008 and replaced with a Condition (7) that refers only to agricultural water quality. EPA provided me with an internal report (Review of Water Quality Guideline Values and Implications for Discharge Limits, by Glen Shultz, Ian Ramsay and Neil Tripodi, 8 May 2008) that they assert was used to inform the last of the TEPs issued to Ensham.

<sup>13</sup> EPA have informed me that this is normal EPA practice with discharges from mines. However, this was not a 'normal' situation.

<sup>14</sup> Since 10 September 2008, Ensham have voluntarily extended their monitoring program beyond Bedford Weir to include all downstream weirs to the Rockhampton Barrage. Ensham have also voluntarily conducted one set of sediment samples in each of the weirs from Bedford Weir to the Rockhampton Barrage.

<sup>15</sup> The Department of Natural Resources & Water now have continuous recording conductivity meters located at Theresa Creek (located at Gregory Highway, operating since 10 Feb 1994), Nogoia River (Duckponds, 2 April 1993), Mackenzie River (Riley's Crossing, 15 July to 9 October 2008), Isaac River (Yatton, 11 September 1995), Mackenzie River (Coolmaringa, 10 November 1999), Dawson

- There was no requirement for the company (or the EPA) to undertake any biological monitoring despite the fact that the discharge was to occur during the dry season when dilution was minimal and the potential impact on the aquatic biota was high.
- The conditions under which the discharge was required to cease - if the rolling median value for the most recent five weeks (of weekly) water monitoring data exceeds specified limits - allows large fluctuations in the measured parameters to occur, and potentially short-term spikes in salinity and toxicant concentrations, which could be detrimental to the downstream aquatic biota. The large fluctuations that did occur in conductivity measured continuously at Riley's Crossing are shown in Figure 6. Use of a rolling median value for compliance, rather than an absolute value to relate to each sampling occasion, is sensible. The issue is the large time period for the median – a more sensible time period would have been a weekly.

Additionally, my assessment is that EPA did not adequately consult with key stakeholders in establishing the TEPs, or inform the community generally about what was happening and what the possible effects could be.

The issue with poor drinking water quality in Tieri and Blackwater was identified through the CHRC regular monitoring program; they appear not to have been informed that this could happen as a result of the mine-affected water discharge. Also I have not been supplied with any evidence of EPA discussions with stakeholders responsible for, or interested in, protecting the health of the aquatic biota in this system.

The lack of general information about what was happening and what the possible effects could be, that was available to the community lead to suspicion and distrust, and eventually to the development of a number of 'conspiracy' theories.

It is my belief that the EPA underestimated the scale of this emergency situation (discharge of a very large volume (138 GL) of mine-affected water over a period of 6-8 months to a river system that was largely not flowing), and as a result misjudged the community reaction to what was happening.

*It is recommended that EPA undertake a review of the procedures used to develop TEPs and publish the results (a new set of guidelines) on the EPA web site. This review should consider the need for (a) criteria for prioritising the importance of the TEP, (b) undertaking a risk assessment to assist in developing the TEP, (c) a checklist that ensures that all beneficial uses of the receiving waterbody are explicitly considered, (d) a better process for identifying and including key stakeholders in the TEP process, (e) a process for informing the community of the situation associated with potentially controversial TEPs, and (f) better processes for ensuring the quality of the TEPs developed (e.g. documenting the reasons for various decisions or judgements).*

Figure 6: Continuous conductivity (uS/cm) measurement at Riley's Crossing between mid June 2008 and mid October 2008 (data provided by DNRW Rockhampton)

#### 4. Assessment of current risks

This section contains my review of the risks to human health, aquatic ecology, agriculture and industry as a result of the mine-affected water in the Nogo-Mackenzie-Fitzroy River system.

##### 4.1 Human health

###### ***Blackwater, Bluff, Tieri, Middlemount and Dysart***

Water is taken from weirs along the Nogo-Mackenzie River to supply drinking water for a number of small towns. Blackwater, Bluff and Tieri obtain their water from Bedford Weir, while the towns of Middlemount and Dysart obtain their water from Bingegang Weir. The water is mostly treated (coagulation, filtration, chlorination) before use, but this treatment does not remove any dissolved material (such as sodium).

Residents of Blackwater and Tieri first expressed concern about the poor taste of the water. Subsequently, it was assessed that there could also be health problems for vulnerable members of the community due to elevated sodium levels.

Figure 7: Plot of conductivity verses distance in the Nogoia-Mackenzie-Fitzroy river system over the period July to November 2008. The rise in conductivity at Eden Bann in August is the result of a high flow (41 GL) from the Isaac/Connors system between 20 July and 30 August 2008, that displaced mine-affected water from Tartrus Weir and water holes in the Mackenzie River and pushed this water through to Eden Bann and the Barrage.

On 26 August 2008, very soon after they were advised of the situation, Queensland Health (2008) issued a media-release advising residents of Blackwater, Bluff and Tieri that the mine-affected water had resulted in an increase in sodium concentrations to levels (around 200 mg/L). And that this could cause problems for a small number of susceptible people (e.g. those with high blood pressure, cardiovascular disease or chronic kidney failure). Further, Queensland Health sensibly recommended that these residents used bottled water until the situation had normalised.

The Australian Drinking Water Guidelines (ADWG, 2004, p442-443) recommend that based on taste considerations, sodium concentrations in drinking water should not exceed 180 mg/L. Further, while they do not propose any health-based guidelines, they do advise that *'people with severe hypertension or congestive heart failure may need to restrict their overall dietary intake of sodium further if the concentration of sodium in drinking water exceeds 20 mg/L'*.

Sodium levels in these drinking waters have exceeded the 180 mg/L level for a considerable period of time, possibly from as early as July 2008, although they appear to have dropped since the discharge ceased in early September 2008<sup>16</sup>.

Additionally, some residents have complained to Central Highland Regional Council (CHRC) of problems with scaling on pots and hot water services (CHRC Submission, 30 October 2008).

In response to a question from me, namely have there been any reported health effects on residents of Blackwater, Bluff and Tieri exposed to drinking water with elevated sodium concentrations, Queensland Health (Paul Florien, submission 7 November 2008) provided the following response: *'Around this time (late August 2008), the Communicable Disease Control Section of the Central Queensland Population Health Unit was aware of outbreaks of viral gastroenteritis in several communities across Central and Central West Queensland, but not specifically Blackwater. Following the release of the advisories, CHRC experienced an increase in complaints, specifically alleging a link between the water and outbreaks of disease in the community. These claims were followed up then and over the following three weeks by the Public Health Physician in contact with Blackwater Hospital.*

*There had indeed been an increase in presentations to hospital with vomiting and diarrhoea, with sudden onset and short duration of illness. Unfortunately, no pathological diagnosis was made, as no samples of vomitus or faeces were collected and submitted for laboratory analysis.*

*It is likely that viral gastroenteritis was responsible for the symptoms. It is highly likely that the decrease in palatability of the water aggravated symptoms and susceptibility to dehydration.'*

#### Assessment

It does not appear that there have been any serious health problems in the townships of Blackwater, Bluff, Tieri, Middlemount and Dysart due to the elevated sodium levels in their drinking water supply. Sodium levels in Tieri's drinking water supply<sup>17</sup> were in excess of 180 mg/L between early June and late October 2008 (CHRC monitoring data). The small number of people concerned about the possible impact of elevated sodium levels on their blood pressure were advised to use alternative drinking water.

Queensland Health has advised that it is possible that the poor quality water did increase the effects of a viral gastroenteritis outbreak in the region in late August 2008.

Additionally, there is considerable evidence that the residents have been adversely affected by the poor taste of their drinking water supply. The conductivity (salinity) of drinking water supplied to the residents of Blackwater, Bluff, Tieri, Middlemount and

<sup>16</sup> Note that while Bedford Weir had received the mine-affected water by as early as March 2008, this water would not have been supplied to the residents of Tieri, Blackwater or Bluff until some 3-4 months later because there is considerable water storage capacity between the Weir and the treatment plants.

<sup>17</sup> And presumably also Blackwater, Bluff, Middlemount and Dysart.

Dysart was in excess of 1,000 uS/cm (600-700 mg/L) for around 6 months (June – November 2008).

Given the poor tasting water, it is reported that many residents resorted to bottled water for drinking. This has potentially cause hardship for particular sectors of these communities (e.g. lower socio-economic group, elderly) who may have been seriously disadvantaged in being able to access and pay for bottled water. The question of who should pay the increased cost is a relevant one.

Additional major concerns are that: (a) downstream drinking water supplies appear not to have been considered by the EPA in issuing the TEP, (b) neither the Central Highlands Regional Council, Queensland Health nor the residents were informed of the situation early enough<sup>18</sup>, and (c) media reports indicate significant community concern about this issue, a lack of trust in Government to fix the issue, and resentment with Ensham.

### **Rockhampton**

Drinking water for the Rockhampton community is taken from the Fitzroy Barrage and treated at the Glenmore Water Treatment Plant before distribution to approximately 66,000 residents. The treatment process involves coagulation, flocculation, sedimentation, filtration and disinfection; activated carbon treatment is sometimes used to remove tastes, odours and potential algal toxins.<sup>19</sup> These processes do not reduce conductivity and activated carbon does not remove a mineral taste.

It appears that the mine-affected water reached the Fitzroy Barrage in early September 2008, and during October essentially stabilised at a conductivity of around 825 uS/cm and sodium concentration around 120 mg/L (Figure 8).

Given the conductivity of the upstream water (around 1,200 uS/cm), it is inevitable that the conductivity (and sodium concentration) of water in the Barrage will increase during November 2008. However, just when the peak will occur and for how long it will last will depend upon when the wet season rains commence.

Rockhampton Regional Council issued media releases on 9 September and 14 October 2008, advising residents of the situation. Additionally, the Mayor and Councillors have also given a number of radio and television interviews.

Queensland Health (submission by Dr Paul Florian, 30 October 2008) have also expressed concern over the deteriorating quality of Rockhampton's water supply and its possible affects on the Rockhampton Hospital and its Dialysis Clinics and Home Dialysis Patients. Haemodialysis units require virtually pure water with very low ionic concentration. Complex water treatment systems are used to achieve this purity, and if the feed water quality changes significantly, there is a real probability that the product water will also change in quality.

Another area of concern is the Central Sterilising Supply Department at Rockhampton Base Hospital, where recently problems have been experienced with a residue forming on Operating Theatre equipment that has passed through the disinfection units. The residue is most likely calcium carbonate. If this persists, the hospital will need to invest in a small treatment plant.

---

<sup>18</sup> The Central Highland Regional Council only became aware of the poor quality water around 21 August 2008, through their routine monitoring of the Tieri water supply (CHRC Submission, 30 October 2008).

<sup>19</sup> See [www.rockhamptonregion.qld.gov.au](http://www.rockhamptonregion.qld.gov.au)

### Assessment

It seems unlikely that any serious health problems will arise as a result of the current (October 2008) increased conductivity and sodium concentrations in Rockhampton's drinking water supply.

These concentrations are likely to increase further during November (and even December if there is a lack of rain). But again, provided medical practitioners and the small number of vulnerable people are well informed, and there is access to bottle water, serious health problems are unlikely to occur.

It is quite possible however that Rockhampton Regional Council will experience a large increase in complaints about the poor taste of the drinking water.

If Rockhampton's water supply decreases further in quality, problems are also expected at the Rockhampton Hospital and its Dialysis Clinics and Home Dialysis service.

Given that water in the Fitzroy Barrage is considerably clearer than normal (due no doubt to coagulation of colloidal particles by the higher calcium and magnesium concentrations), there is a real possibility that algal blooms will occur in the Barrage. The Rockhampton Regional Council are aware of this possibility and have contingency measures in place to minimise the risks to human health from blue-green algal toxins in drinking water supplies.

Additional concerns are that: (a) downstream drinking water supplies for the major population centre of Rockhampton appear not to have been considered by the EPA in issuing the TEP, (b) neither the Rockhampton Regional Council, the Health Department nor the residents were informed of the situation early enough, and (c) media reports indicate significant community concern about this issue, a lack of trust in Government to fix the issue, and resentment with Ensham.

Figure 8: Conductivity and sodium concentration in the Rockhampton Barrage over the period September 2007 to October 2008. The insert shows the situation between September and late October 2008.

#### 4.2 Aquatic ecosystems<sup>20</sup>

The ecological functioning in the Fitzroy Basin is primarily driven by flow, which is characterised by two main phases - wet season monsoon flood events between December and March, and low or no flow periods during the rest of the year. The wet season monsoon flows are the most dominant feature of the flow regime in the Fitzroy catchment. These flows are highly variable and unpredictable (amongst the highest variability of any rivers in the world) and as a consequence the biota has evolved a number of strategies to adapt to this environment.

The **wet season flow events** serve a number of ecological functions including:

- fish migration – flow events enable dispersal past minor barriers (e.g. shallow riffles) and into temporary marginal habitats within the high flow channel. Studies have shown a number of fish species, such as Hyrtls tandan (*Neosilurus hyrtlii*), respond to early wet season flow events for migration into suitable spawning grounds,
- fish spawning – the spawning of a number of fish species, such as the endemic Fitzroy golden perch (*Macquaria ambigua oriens*) and Leathery Grunter (*Scortum hillii*), are triggered by wet season flow events (spawning may occur over only 1-2 flow events) (Roberts et al., 2008),
- fisheries recruitment – the recruitment of a number of diadromous and marine fish species (e.g. Barramundi (*Lates calcarifer*) and Threadfin Salmon (*Polydactylus macrochir*)) and prawn (*Penaeus merguensis*) populations has been demonstrated to be highly correlated with high flow events,
- reproduction of other aquatic organisms – major breeding events of many animals, such as waterbirds, are associated with extensive floodplain flows rather than elevated in-stream flows,
- primary and secondary production - temporary expansion of river into marginal habitats brings additional nutrients and organic material into the river system stimulating additional production. The wetting of marginal habitat also leads to germination of flood-dependant vegetation (e.g. Coolibah (*Eucalyptus coolabah*) and paperbarks (*Melaleuca* spp.)),
- mixing of the water column and flushing and refreshing of waterholes – larger flow events flush out large waterholes common in the Fitzroy Basin. These flushes refresh waterhole water quality and reset many algal and zooplankton populations,
- temporal diversity in aquatic habitat – temporary expansion of river into marginal habitats provides a diversity of refugia habitats utilised by many animals, including fish larvae and zooplankton (e.g. Fabbro and Duivenvoorden 1996).

**Low and no flow periods**, which characterise the flow regime for much of the year, also influence a number of ecological functions including:

<sup>20</sup> The description of the ecological functioning of the Fitzroy River was supplied by Dr Bernie Cockayne (DNRW) and Dr Leo Duivenvoorden (Central Queensland University)..

- fish spawning – stable low flow conditions provide ideal conditions for many fish species, particularly small bodied fish which attach eggs to structures, such as river bank edges, macrophytes and woody debris,
- reproduction of other aquatic organisms – many turtle species utilise sand banks exposed during low/no flow periods as egg laying sites,
- waterholes as refugia – almost all in-stream plants and animals rely on waterholes during some stage of their lifecycle. Waterholes provide a refuge against drought conditions, high water temperatures and predation from other animals, and are a dominant feature during the low - no flow period,
- riffles as habitat – riffles are generally the most productive of habitats and support a high diversity of plants and animals common in the Fitzroy River system (e.g. the ‘bum breathing’ Fitzroy River turtle (*Rheodytes leucops*),
- water quality decrease during low flow conditions can occur, particularly in the smaller streams of the catchment as pools start to dry up.

There are a number of **man-made issues** potentially threatening the aquatic ecology in the Fitzroy River system, including:

- changes to the flow regime – regulation of the Fitzroy River system has had a major effect on the magnitude, duration, timing and frequency of flows during the low flow period, and to the small to medium flow events during the wet season,
- barriers to fish migration – weirs and dams can interfere the migration of fish species, and have caused reduction (and possible extinction) of some fish species in certain regions of the river system (e.g. barramundi to many areas upstream of the Fitzroy Barrage and Golden Perch to many areas of the Nogoa-Mackenzie River system),
- changes to habitat – the water impoundments behind the dams and weirs built on the Nogoa-Mackenzie-Fitzroy River system have drastically reduced the habitat available for many native species, while at the same time providing ideal conditions for many exotic species (e.g. *Hymenachne amplexicaulis*),
- invasion of weeds – these have had a dramatic effect of riverine biodiversity (Houston and Duivenvoorden, 2003; Duivenvoorden et al., 2008),
- Water quality contamination - through both mining (e.g. acid mine drainage and agricultural activities (Dr Leo Duivenvoorden, Central Queensland University, Personal Communication, November 2008).

Thus, the mine-affected water discharged to the Nogoa-Mackenzie-Fitzroy River system, largely during the dry season of 2008, added an additional threat to the aquatic ecosystem, which has already been modified by the above pressures.

The ‘health’ of an aquatic ecosystem is generally assessed by undertaking a biological monitoring program, most often in Australia using macroinvertebrates as the biological indicators, and less commonly other biological indicators, such as algae, fish, platypus, turtles and bacteria.

In attempting to review the potential adverse effects of the mine-affected water on the aquatic biota in the Nogoa-Mackenzie-Fitzroy River system, I have been severely hampered by a serious lack of biological-ecological information. In particular, there is very limited baseline information on this river system, and there was no biological

monitoring undertaken during the period the Ensham mine-affected water was discharged<sup>21</sup>.

Given the lack of biological monitoring data for this system, I have had to resort to other less satisfactory information sources to assess the current situation. A report by 4T Consultants (2008) (commissioned by Ensham) has been quite helpful.

### ***Fish populations***

No comprehensive surveys of the fish populations in the Fitzroy River system appear to have been undertaken. Biosecurity Queensland undertook a limited survey of the health of fish in Bedford and Tartrus Weirs in September 2008, the results of which are discussed below.

DNRW scientists have been studying the spawning requirements of the endemic flow-spawning fish species Fitzroy Golden Perch (*Macquaria ambigua orientalis*) and Leathery Grunter (*Scortum hillii*) since 2003 as part of the Fitzroy environmental flows assessment program (EFAP) activities<sup>22</sup>.

Monitoring has been undertaken during wet seasons in response to natural and artificial flood events, such as the first post winter flow event. Both regulated and unregulated sections of the river system are being studied. Important outcomes of this work are: (a) small flows at the beginning of the wet season are critical for spawning migration and potentially effect subsequent spawning success, (b) spawning occurs only in response to flow events when water temperatures are greater than 23.5°C, (c) spawning also only occurs during 1 or 2 events per year, (d) no spawning occurred in the regulated sections of the Nogoa-Comet-Mackenzie River system (possibly because there a very few adult fish in these sections).

### ***Salinity effects***

The available evidence (e.g. Hart et al., 1990, 1991) suggests that most Australian fish species are relatively tolerant of salinity increases, and certainly adult fish in the Nogoa-Mackenzie-Fitzroy system would be unlikely to be adversely affected by salinities up to around 1,500 µS/cm.

Unfortunately, the effects of higher salinity on spawning, survival of eggs and larvae, and migration cues of fish present in the Fitzroy River system are not known. However, it is expected that such effects would occur at lower salinity levels than effects on adult fish (ANZECC, 2000; Dr Ben Kefford, personal communications, November 2008). Tolerance studies on other fish species (trout cod, Murray cod) suggest that adverse effects are likely on early life stages (eggs, larvae) at salinities around 1,000-1,500 µS/cm (Dr Ben Kefford, Personal Communication, November 2008).

For Fitzroy Golden Perch, no work has been done on the salinity sensitivity of this fish species, or the effects of higher salinity on spawning, eggs and larvae and migration cues (Dr Bernie Cockayne, Personal Communication, November 2008). However, given that this species spawns in the very early part of the wet season, it seems quite possible that this coming wet season could result in serious adverse effects on Fitzroy Golden Perch spawning success because of the poor water (high salinity) that will be flushed out of the river.

Also of concern is the possible effect of the higher salinity water on other more

---

<sup>21</sup> A biological monitoring program, coordinated by the EPA, is now (November 2008) underway in the Nogoa-Mackenzie-Fitzroy system.

<sup>22</sup> Dr B. Cockayne, DNRW, Personal Communication, November 2008.

abundant fish species in the Fitzroy catchment, particularly the smaller bodied fish species. These species rely on both good water quality and stable low flow conditions for successful spawning.

#### *Toxic effects*

Resulting from a report of catfish in Tartrus Weir with redness of all fins, Biosecurity Queensland undertook a limited survey of Blue Catfish (*Arius graeffei*) from Bedford and Tartrus Weirs in September 2008 (Biosecurity Queensland, 2008).

The fish species were subject to pathological analysis and for exposure to heavy metals and pesticides.

The results indicated that the fish from these Weirs were in poor health. The gill pathology was consistent with poor water quality, possibly exposure to elevated heavy metal concentrations, and not to infectious bacterial or viral fish disease. The fish tissue was found to contain elevated levels of iron, aluminium and zinc. There was no evidence of exposure to a range of pesticides (organochlorines, pyrethroid, endosulphan).

It is not possible to relate the results of this study back to the mine-affected water because there is no information on: (a) water quality in the weirs at the time of sampling (e.g. was dissolved oxygen concentration low?), (b) the age of the fish, necessary to assess the potential bioaccumulation of heavy metals, (c) the health or heavy metal concentrations of the fish species before the mine-affected water was added to the system.

#### **Macroinvertebrate populations**

Macroinvertebrate surveys are conducted annually by the Aquatic Ecosystems Unit of the Department of Natural Resources and Water (DNRW). The latest report of the situation in 2007 has not yet been publically released, but a draft was made available for this review (Steward, 2008).

During 2007, macroinvertebrates were sampled once in May-June at 25 sites (8 reference sites, 16 test sites, 1 long-term site) in the Fitzroy basin. These regional surveys are designed to provide an assessment of the biological condition of large bioregions, and not individual catchments or rivers. Hence, the use of this biological information for assessing the ecological condition of these rivers prior to the mine-affected water discharge is questionable.

Based on available information on the sensitivity of macroinvertebrates to increased salinity levels (Hart et al., 1990, 1991; Kefford et al., 2008; Dunlop & McGregor, 2007), it seems that adverse effects on macroinvertebrates are unlikely to occur at levels below around 1,000  $\mu\text{S}/\text{cm}$ . However, this statement is based on data that mostly relate to short-term studies, and not to continual exposure over a 7-8 month period.

Advice from Dr Ben Kefford (RMIT University, Melbourne, November 2008) suggests that given the quite low salinity (200-300  $\mu\text{S}/\text{cm}$ ) normally in this system, a rise to levels of 1,000-1,500  $\mu\text{S}/\text{cm}$  would adversely affect macroinvertebrate community structure, especially if examined at the species level. The taxa most affected would be EPT species, especially mayflies.

### **Other biota**

No information was available to assess the possibility that other biota (e.g. frogs, platypus and turtles) have been adversely affected by the mine-affected water.

### **Ecosystem changes**

The clarity of the river water has increased since mine-affected water has been released to the Nogoa-Mackenzie-Fitzroy river system. This reduced turbidity (increased clarity) is the result of coagulation and settling of particulate matter responsible for the turbidity, due to the elevated concentrations of calcium and magnesium in the mine-affected water. Grace et al. (1997) found that calcium and magnesium concentrations in excess of around 30 mg/L clarified water in the Darling River.

The increased clarity of the water in the river system could potentially have resulted in major changes to the aquatic ecology, including increased algal production, increased predation and changes to important food webs (what eats what). Unfortunately, again there is no information on which to make an assessment of whether any such changes have occurred and if they did just how important they are.

### **Assessment**

It is clear that there have not been any catastrophic effects (e.g. major fish kills) on the fish population in the Nogoa-Mackenzie-Fitzroy River system during the time the Ensham mine-affected discharge occurred. This is consistent with the available evidence suggesting that most Australian adult fish species are relatively tolerant of increased salinity, and unlikely to be adversely affected by salinities up to around 1,500  $\mu\text{S}/\text{cm}$ .

However, this is not true for the effects of increased salinity on the early life stages of fish (e.g. survival of eggs and larvae), where the small amount of available evidence suggests that salinities of 1,000-1,500  $\mu\text{S}/\text{cm}$  are likely to cause adverse effects.

It seems quite possible that this coming wet season could result in serious adverse effects on the spawning success of Fitzroy Golden Perch because of the poor water (high salinity) that will be flushed out of the river during the early part of the wet season, exactly the time when this species spawns.

*It is recommended that the EFAP surveys to be undertaken by DNRW this coming wet season are expanded to ensure that the effects of the flushing of higher salinity water on fish (and particularly Fitzroy Golden Perch) spawning and recruitment are studied.*

The available information on the sensitivity of macroinvertebrates to increased salinity levels suggests that adverse effects are unlikely to occur at levels below around 1,000  $\mu\text{S}/\text{cm}$ . However, this level is based on data that mostly relate to short-term studies, and not to continual exposure over a 7-8 month period. Advice has been obtained suggesting that, given the quite low salinity (200-300  $\mu\text{S}/\text{cm}$ ) normally found in this system, a rise to levels of 1,000-1,500  $\mu\text{S}/\text{cm}$  would adversely affect macroinvertebrate community structure, especially if examined at the species level. The taxa most affected would be EPT species, especially mayflies.

The results of a study by Biosecurity Queensland indicated that catfish sampled from Bedford and Tartru Weirs were in poor health. However, it was not possible to relate these back to the mine-affected water discharged to the river system.

*It is recommended that the Biosecurity Queensland study of the 'health' of the fish in*

*weirs be repeated, with other fish species and other storages included, and the study design improved.*

There is insufficient information available to make an assessment of potential adverse effect on other biota, such as frogs, platypus and turtles.

Again there is insufficient information available to assess whether the increased clarity of the water in the river system as a result of the mine-affected discharge, has resulted in major changes to the aquatic ecology, including increased algal production, increased predation and changes to important food webs (what eats what).

The response of relevant Government agencies to assessing the possible impacts of the mine-affected water on the riverine biota has been tardy to say the least. The EPA is currently (end October) gearing up to undertake a comprehensive study of the water quality, sediments and biota in the system (see Section 6 for discussion).

### **4.3 Agriculture**

The mine-affected water is currently being used for two main agricultural activities – stock watering and irrigation.

#### Stock watering

It is highly unlikely that the salinity levels experienced in the Nogoia-Mackenzie-Fitzroy system over the past 8 months have caused any major problems for stock. However, the reports that stock has been reluctant to drink the mine-affected river water are probably well founded given the very low salinity the animals would have been used to.

#### Irrigation

It is unlikely that the salinity levels experienced in the Nogoia-Mackenzie-Fitzroy system over the past 8 months have caused any major problems for irrigated agricultural enterprises. This aspect is well discussed in the 4T Consultants (2008) report.

#### *Assessment*

My assessment is that it is unlikely that the Ensham mine-affected water has caused any major problems for agriculture. The salinity levels were not high enough to cause any long-term problems.

### **4.4 Industry**

Two main industries are using the mine-affected water – the coal mines and the Stanwell Power Station.

#### **Coal mines**

Coal mines in the Bowen Basin use water for four main purposes: coal handling and preparation plants, dust suppression, in underground mining and in industrial areas. Recently, Moran et al. (2006) surveyed water and salt management in a number of coal mines in the northern Bowen Basin, and concluded that (a) there was no evident relationship between coal production and the use of fresh or re-cycled water, and (b) there was considerable potential for improved water management.

Some 8 of the 15 largest coal mines in the Bowen Basin obtain their water from the Nogo-Mackenzie-Fitzroy river system (Table 4).

### *Assessment*<sup>23</sup>

#### Coal processing

It seems there would be no significant constraints to this use at EC levels up to around 1,500  $\mu\text{S}/\text{cm}$ . Most plant operators prefer to have a consistent water quality and are somewhat less concerned about the actual values. There is some evidence that the flotation process can be adversely impacted by increased concentrations of specific ions (e.g. magnesium) as opposed to the overall salinity. A salinity of around 1,300  $\mu\text{S}/\text{cm}$  should not cause problems, provided it was not dominated by magnesium ions. Additionally, increased salinity of the raw water will increase maintenance costs. There is some evidence suggesting that the increase in maintenance cost is linear with increase in salinity (Moran et al., 2008).

**Table 4: Coal mines sourcing raw water from the Nogo-Mackenzie-Fitzroy river system**

Mine	Company	Primary water source
Blackwater	BHP Billiton Mitsubishi Alliance	Bedford Weir
Curragh/Curragh North	Wesfarmers Curragh	Bedford Weir
Peak Downs	BHP Billiton Mitsubishi Alliance	Bingegang Weir
Ensham	Ensham Resources Ltd	Nogo River below Fairbairn Dam
Oaky Creek, No 1 & North	Xstrata Coal Queensland	Bedford Weir
German Creek/Capcoal	Anglo Coal	Bingegang Weir
Norwich Park	BHP Billiton Mitsubishi Alliance	Bingegang Weir
Saraji	BHP Billiton Mitsubishi Alliance	Bingegang Weir

Source: Mining 2006 Update - Queensland Mining and Petroleum, November 2006.

#### Dust suppression

Many mine sites routinely use water with considerably higher salinity than that currently in the Nogo-Mackenzie-Fitzroy system. Thus, it is not considered there would be any problems in using this currently higher salinity water for dust suppression.

#### Underground use

All underground coal mines in Australia use raw water (in some cases potable water) and not re-cycled water, for three reasons: (a) worker safety, (b) corrosion both inside and outside machines (most underground machinery is cooled with flow through water systems), and (c) hydraulic ram (roof support) performance.

It seems unlikely that use of raw water with salinity around 1,300  $\mu\text{S}/\text{cm}$  for less than 12 months would cause major problems with underground mines. However, increased costs due to increased corrosion could be a problem.

<sup>23</sup> This assessment has been informed by the ACARP report prepared by Moran et al. (2008) and discussions with Colin Moffett (General Manager Technical, Ensham Resources).

### ***Stanwell Power Station<sup>24</sup>***

Stanwell Corporation relies on good quality water from the Fitzroy River Barrage for its evaporative cooling towers. The Corporation holds an annual allocation of 24 GL located in Eden Bann weir, with the water pumped to the Stanwell Power Station site from a pump station located on the Barrage at Laurelbank. Since the power station was constructed, annual usage has been typically in the range of 18 to 20 GL.

The mean conductivity (weekly records) of the raw Fitzroy River water delivered to the power station site was 213  $\mu\text{S}/\text{cm}$  (maximum 406  $\mu\text{S}/\text{cm}$ ) over the period March 1993 to December 2007. These salinity levels have allowed the cooling systems to be operated with recycling levels of between seven and ten. This has allowed SPS to comply with the water discharge Development Approval (DA) limits for total dissolved salts of 1,450 mg/L and chloride concentration of 400 mg/L for the 'blowdown' or 'bleed' water released from the site. Typically, 1,500 to 2,500 ML of 'blowdown' water is released annually to Quarry Creek – equivalent to a daily release rate of between 4 and 7 ML/day. Water from Quarry Creek flows on to Neerkol Creek and typically disperses onto the flood plains around Gracemere.

An increase in the salinity of the input water supply results in fewer cycles of concentration being achievable in the cooling systems within the water quality constraints of the DA. Consequently, to achieve the same levels of electricity generation, larger volumes of blowdown are required along with an equivalent increase in the volumes of raw water sourced from the Fitzroy River.

When it was identified that higher salinity levels were likely to be seen in the raw water supplied to the power station, Stanwell Corporation sought a Transitional Environmental Program from the EPA to allow higher salinity 'blowdown' water to be discharged from their site.

Currently, Stanwell Power Station is operating within the limits of the TEP. The current levels of electricity generation, using raw water at the plant (November 2008) with a conductivity of 820  $\mu\text{S}/\text{cm}$ , are producing daily cooling water blowdown volumes in the order of 30 ML – significantly above the original DA limit of 18 ML/day. A number of mechanical modifications have been made to the cooling system plant to allow these volumes to be handled. Since the raw water conductivity has not exceeded 1000  $\mu\text{S}/\text{cm}$ , no changes have been made to the chemical characteristics of the cooling water blowdown.

To date, there has been no impact on electricity generation activities and, while it is unclear how high raw water salinity levels may rise, Stanwell Corporation do not expect any impact on electricity generation in the near future (Stanwell Corporation submission, 5 November 2008).

As part of the TEP, Stanwell is also undertaking extensive environmental monitoring of impacts of the changed blowdown arrangements within the Quarry, Neerkol and Scrubby Creek catchment. This includes independent monitoring of physical and chemical parameters in surface and ground waters in the catchment and at background locations. Detailed biological assessment is also being conducted including at a number of locations throughout the catchment. Hydrology, groundwater recharge and any associated impacts that may be associated with irrigation of various crops with this water is also being considered. This monitoring is being completed in consultation with the EPA and is intended to run until April 2009.

---

<sup>24</sup> This assessment has been informed by information provided by Steve Kerr (Principal Chemist, Stanwell Power Station, 4 November 2008).

Stanwell is also communicating regularly with the broad community and with specific stakeholders who may be impacted as a result of higher discharge volumes.

#### *Assessment*

There has been no impact on electricity generation activities to date. Additionally, Stanwell Corporation expect to be able to handle likely salinity increases in their raw water over the next month or so, and do not expect any impact on electricity generation.

However, it is an unsatisfactory situation that Stanwell Power Station has had to apply for a TEP to accommodate the higher volumes and increased salinity in their 'blowdown' water discharge because of a situation that has arisen further upstream.

## **5. Assessment of possible management options**

A number of options have been proposed to manage the current water quality problems in the Nogoia-Mackenzie-Fitzroy system<sup>25</sup>. These are presented in Appendix A, together with the advantages and disadvantages of each.

The most feasible options are discussed in this section.

### ***5.1 Options to improve town water supplies for Blackwater, Bluff, Tieri, Middlemount and Dysart***

#### ***Option A – Dilution of existing water in Bedford and Bingegang Weirs***

This Option (Option 2a in Appendix A) would see the normal ROP normal ROP operating arrangements for Fairbairn Dam and downstream weirs applying, but with (a) additional management of released from Bedford and Bingegang weirs to improve water quality, and (b) small scale releases from Fairbairn Dam to dilute the water that is already present in the weirs.

The first part of this Option would see as much as possible of the lower quality water stored at depth in the weirs released through regulation of flow from the outlet works of weirs. This strategy would apply for releases associated with: (a) topping up downstream storages, and (b) natural inflows that trigger seasonal base flow environmental releases including overflows. Details of this Strategy are contained in the Interim Operational Strategy for the Nogoia Mackenzie Water Supply Scheme - 31 October 2008.

Added to this strategy would be the release of relatively small quantities of seasonally assigned water (water that is ordered but not used) from Fairbairn Dam to improve the quality of water in the weirs. These releases would not flush the weirs, but would certainly improve the quality.

Small natural inflows are also likely in the short term. Historically, by end of December there is about a 36% chance of 30,000 ML natural inflow to Bedford Weir and a 25% chance of 60,000 ML.

#### *Assessment*

This is a sensible and feasible Option, and should be implemented as soon as possible, given the time for water to get from Fairbairn Dam to dilute that in Bedford

---

<sup>25</sup> I am indebted to DNRW Rockhampton staff for producing many of these options and the list of advantages and disadvantages.

Weir (3 weeks). Implementation of this Option would have community support in that the Government would be seen to be doing something positive

If summer rains do not occur it will be necessary to invoke other Options (see Appendix A, Options 4 or perhaps even Option 3) to ensure the township water supplies do not deteriorate further.

### ***Option B – Emergency options***

Three options have been identified that could be implemented if the water quality in Bedford and Bingegang Weirs deteriorates further. These are:

- Pump poorer quality water from Bedford Weir and store in private farm dams for later use or release back when flows are higher (Appendix A - Option 4),
- Trucking 'drinking' water supply supplies (Appendix A - Option 5a),
- Mobile desalination plant (Appendix A - Option 5b).

These are fully discussed in Appendix A.

## ***5.2 Options for the lower Fitzroy and the Fitzroy Barrage***

### ***Option C – Normal ROP operational arrangements, with additional release management of Eden Bann Weir (Appendix A – Option 6b)***

This Option aims to achieve better water quality at the intake works for Rockhampton Regional Council and Stanwell Power Station than would be achieved if just the normal operational rules applied, and may result in operation outside the existing ROP rules.

The normal ROP operating arrangements for Eden Bann Weir and the Fitzroy Barrage would apply, except where it is otherwise determined that a release: (a) should be delayed because it was likely that it would worsen the quality of water at the Rockhampton Regional Council and Stanwell Power Station intakes, or (b) should occur because it was likely that the release would improve the quality of water at the Rockhampton City Council and Stanwell Power Station intakes. The strategy details are contained in the Interim Operational Strategy for the Lower Fitzroy and Fitzroy Barrage water supply schemes dated 28 October 2008.

The water quality in Eden Bann Weir and the Fitzroy Barrage, while elevated compared to normal water quality levels, has been and remains considerably better than the quality in the Mackenzie River Weirs. However, it appears that there has been no consideration of other possibilities that could result in more mine-affected water from upstream being flushed into Eden Bann Weir and the Fitzroy Barrage, for example a small flow event in the Isaac/Connors system could flush mine-affected water reportedly in that system (S. Christensen, Personal Communication, October 2008) into Tartrus Weir, and then flush this water plus the mine-affected water current in Tartrus Weir further downstream.

Based on historical data there is a quite reasonable probability that large natural flows will occur in this system. For example, by end of December there is about a 50% chance of in excess of 122 GL natural inflow to Eden Bann Weir<sup>26</sup>, a 75% chance of 162 GL by end of January, and 75% chance of about 440 GL by end of February.

---

<sup>26</sup> Note – Eden Bann Weir retains a volume of 40 GL at full supply level.

### *Assessment*

This is a sensible and feasible Option and should be adopted now.

It is also recommended that a contingency plan be developed during November to handle the possibilities that: (a) additional mine-affected water will be flushed into this system from the Isaac/Connors system, and (b) that the expected normal wet season flows will not occur and the dilution and flushing of mine-affected water from Eden Bann Weir and the Fitzroy Barrage does not occur.

### **5.3 Options for reducing the risk to the aquatic biota**

The Options discussed in the Sections above all focus on management actions to improve water quality in the various storages, mainly with the aim of improving drinking water quality.

As discussed in Section 4.2, the Nogo-Mackenzie-Fitzroy River system currently has mine-affected water in over 400 km of its length from at least Bedford Weir to the Fitzroy Barrage. Unfortunately, the lack of data and information has made it difficult to properly assess the effects of this mine-affected water on the aquatic biota in the system. However, the small amount of evidence available suggests that there will have been adverse impacts of the macroinvertebrate communities and probably of some fish species. The increased clarity of the water currently in the river system will have resulted in changes to the aquatic ecology, but the implications of these changes can only be speculated at this stage.

Obviously, the management options being considered will result in some improvement in the quality of the water in the river system between the storages, although the actual level of improvement has not been quantified.

### *Assessment*

It is both surprising and disappointing that no Options have been formulated that specifically target the improvement of water quality in the Nogo-Mackenzie-Fitzroy River system, such that the risks to the aquatic biota are minimised.

It is recommended that options to improve water quality in the Nogo-Mackenzie-Fitzroy River system, not just the storages, be developed with some urgency during November 2008.

### **5.4 Recommended management options**

A number of sensible and feasible management options have been identified by the Technical Working Group (TWG) to address the current water quality problems in the Nogo-Mackenzie-Fitzroy system. If implemented these management actions will have some positive effect on both drinking water quality and river health, and will show to the community that Government is serious about this issue and prepared to do something positive about it.

However, the ultimate flushing of the mine-affected water currently in the Fitzroy system will only occur with the large flows normally expected in the wet season (December-March).

It should be noted that all the management options currently being considered to alleviate the current water quality problems are restricted to a very large extent by the water use rules (ROP) for the Nogo-Mackenzie River system, rules that appear to

be largely dictated by agricultural and industrial use of the water. *These rules may need to be modified in the future to consider other legitimate users of water, such as the environment and townships, and the possible need for a State-owned contingency licence to a certain proportion of the water in Fairbairn Dam.*

*It is recommended that Option A be implemented as soon as possible, given the time for water to get from Fairbairn Dam to dilute that in Bedford Weir (3 weeks). Implementation of this Option would have community support in that the Government would be seen to be doing something positive.*

*It is recommended that the Central Highland Regional Council establish a Task Force to develop a contingency plan for addressing the drinking water quality issue for Blackwater, Bluff, Tieri, Middlemount and Dysart should the Bedford and Bengegang Weirs not be adequately flushed during this coming wet season. Such a contingency plan will involve more detailed examination of Option B above, and Options 4 or perhaps even Option 3 in Appendix A.*

*It is recommended that Option C be implemented as soon as possible.*

*Additionally, it is recommended that a contingency plan be developed by DNRW during November to handle the possibilities that: (a) additional mine-affected water will be flushed into this system from the Isaac/Connors system, and (b) that the expected normal wet season flows will not occur and the dilution and flushing of mine-affected water from Eden Bann Weir and the Fitzroy Barrage does not occur.*

*It is recommended that an emergency water management plan be developed with some urgency during November 2008 to improve water quality in the vast bulk of the Nogoia-Mackenzie-Fitzroy River system between the storages. This plan will need to be innovative and not constrained by the current restrictive ROP rules.*

## **6. Assessment of the proposed EPA monitoring program**

The response of relevant Government agencies to assessing the possible impacts of the mine-affected water on the riverine biota has been tardy, so much so that the Premier, in October 2008, directed the EPA to establish a whole-of-government monitoring program to assess the potential impacts of mine-affected floodwater discharged from the Ensham mine on the Nogoia-Mackenzie-Fitzroy River system.

A draft Project Plan (Fitzroy Basin Water Quality Monitoring: Assessing the impact of Ensham floodwater release, Version 1.0, 28 October 2008) has been prepared. The stated purpose of the monitoring program is *'to assess the potential impact(s) of mine water discharged from the Ensham Resources coal mine on waterways and related environmental values in the Fitzroy Basin; the environmental values of particular interest include: aquatic ecosystems, primary industries (irrigation and stock watering), and drinking water.'*

I have reviewed the draft and provided comments to the EPA (29 October 2008). aimed at strengthening the program. The most relevant comments were:

- The study design is a traditional one, and includes sampling of water quality, sediment and biological indicators at a number of control and impacted sites over time,
- The selection of water quality, sediment and biological (macro-invertebrates, fish) indicators is sensible, although the use of turtle indicators needs to be better justified,

- The suggested frequency of sampling (WQ - fortnightly; sediments – quarterly; biology – quarterly) is reasonable,
- The selected indicators and the frequency of sampling should be reviewed after the first full round of measurement of all indicators is completed,
- There is a need for a conceptual diagram indicating how the study will be able to assess any potential impacts from the mine (compared with effects due to other influences),
- The selection of the location of the control and test site needs further justification,
- The analysis of the collected data to show whether adverse effects have (or are) occurred is too vague. Additional information on the following is required:
  - *Surface water* - It is proposed to compare the surface water quality with ANZECC Guidelines for the Protection of Aquatic Life and with the Australian Drinking Water Guidelines for drinking water to decide if adverse effects have occurred. This should be sufficient provided that the uncertainty in the measured indicators is available – this will require that replicate water samples are collected and analysed.
  - *Sediments* - It is proposed to compare the sediment quality with the ANZECC guidelines. This should be sufficient to assess whether heavy metals levels in the sediments are such that they could cause toxic effects to the biota. Again, the comparison of measured data with the guidelines (thresholds) would be more robust if the uncertainty in the measured indicators is available.
  - *Biological indicators* – This is the area that still needs considerable work. Just how the data from the test sites will be assessed is still unclear. Comparison with control (reference) sites is commonly employed, however the draft has little detail on how this will be done and whether the data will be sufficient to be able to detect ecologically meaningful effect sizes. Power analysis was mentioned in the draft but no detail was provided.
- It is not clear in the draft who (agency) will be doing what work and what their credentials are.
- It would be useful to list who has been consulted in developing this program.
- It is not clear how this monitoring program with other monitoring that is also going on in the Fitzroy catchment (e.g. DNRW, FBA).
- The timescale of the study is unclear.
- As noted above, because there is little baseline information available, this study will be challenged in determining if any short-term biological impacts have occurred due to the mine-affected water. For this reason, *it is recommended that the study continues for at least 2 years (3 wet-dry cycles) so that any recovery in the condition of the biota can be measured.* The information on the system that will be collected during this time will also be vital in the development of a more comprehensive Fitzroy catchment-wide monitoring and assessment program.

A full assessment of the final monitoring and assessment program will be made in a separate report.

## 7. Conclusions

The conclusions of this review are summarised below under each of the Terms of Reference. Additionally, I have provided comments in Section 7.4 on the adequacy of Government actions in addressing this issue, and on what changes might be needed in those cases where Government response was less than adequate.

### **7.1 Risks to human health, aquatic ecology, agriculture and industries**

#### **Human health**

##### Blackwater, Bluff, Tieri, Middlemount and Dysart

There is no evidence of any serious health problems in the above townships due to the elevated sodium levels in their drinking water supply. However, it is possible that the poor quality water did increase the effects of a viral gastroenteritis outbreak in the region in late August 2008.

There is considerable evidence that the residents have been adversely affected by the poor taste of their drinking water supply.

Additional major concerns are that: (a) downstream drinking water supplies appear not to have been considered by the EPA in issuing the TEP, (b) neither the Central Highlands Regional Council, Queensland Health nor the residents were informed of the impending problems early enough<sup>27</sup>, and (c) media reports indicate significant community concern about this issue, a lack of trust in Government to fix the issue, and resentment with Ensham.

##### Rockhampton

It seems unlikely that any serious health problems will arise as a result of the current (October 2008) increased salinity and sodium concentrations in Rockhampton's drinking water supply. These concentrations are likely to increase further during November (and even December if there is a lack of rain), but provided medical practitioners and the small number of vulnerable people are well informed, and there is access to bottled water, serious health problems are unlikely to occur.

It is quite possible that Rockhampton Regional Council will experience a large increase in complaints about the poor taste of the drinking water, at least until the Fitzroy Barrage is fully flushed.

If Rockhampton's water supply decreases further in quality, problems are also expected at the Rockhampton Hospital and its Dialysis Clinics and Home Dialysis service.

There is a real possibility that blue-green algal blooms will occur in the Fitzroy Barrage in the next month or so, given that water in the Barrage is considerably clearer than normal. However, the Rockhampton Regional Council are aware of this possibility and have contingency measures in place to minimise any risks to human health from blue-green algal toxins in drinking water supplies.

Additional concerns are that: (a) downstream drinking water supplies for the major population centre of Rockhampton appear not to have been considered by the EPA in issuing the TEP, (b) neither the Rockhampton Regional Council, Queensland

---

<sup>27</sup> The Central Highland Regional Council only became aware of the poor quality water around 21 August 2008, through their routine monitoring of the Tieri water supply (CHRC Submission, 30 October 2008).

Health nor the residents were informed of the situation early enough, and (c) media reports indicate significant community concern about this issue, a lack of trust in Government to fix the issue, and resentment with Ensham.

### ***Aquatic biota***

Review of the possible effects on river health has been hampered by a dearth of relevant information.

It is clear that there have not been any catastrophic effects (e.g. major fish kills) on the fish population in the Nogoa-Mackenzie-Fitzroy River system during the time the Ensham mine-affected discharge occurred. This is consistent with the available evidence suggesting that most Australian adult fish species are relatively tolerant of increased salinity, and unlikely to be adversely affected by salinities up to around 1,500  $\mu\text{S}/\text{cm}$ .

However, this is not true for the effects of increased salinity on the early life stages of fish (e.g. survival of eggs and larvae), where the small amount of available evidence suggests that salinities of 1,000-1,500  $\mu\text{S}/\text{cm}$  are likely to cause adverse effects. *It seems quite possible that this coming wet season could result in serious adverse effects on the spawning success of Fitzroy Golden Perch because of the poor quality water (high salinity) that will be flushed out of the river during the early part of the wet season, exactly the time when this species spawns.*

The results of a study by Biosecurity Queensland indicated that catfish sampled from Bedford and Tartrus Weirs were in poor health. However, it was not possible to relate these back to the mine-affected water discharged to the river system. This study should be repeated with other fish species and other storages included and a better study design.

There is no evidence of adverse effects on the aquatic biota due to heavy metals in the mine-affected water.

The available information on the sensitivity of macroinvertebrates to increased salinity levels suggests that adverse effects are unlikely to occur at levels below around 1,000  $\mu\text{S}/\text{cm}$ . However, this level is based on data that mostly relate to short-term studies, and not to continual exposure over a 7-8 month period. Advice has been obtained suggesting that a rapid rise in salinity to levels of 1,000-1,500  $\mu\text{S}/\text{cm}$  would adversely affect macroinvertebrate communities (particularly mayflies), given the quite low salinity (200-300  $\mu\text{S}/\text{cm}$ ) they normally experience.

There is insufficient information available to make an assessment of potential adverse effect on other biota, such as frogs, platypus and turtles.

Again there is insufficient information available to assess whether the increased clarity of the water in the river system as a result of the mine-affected discharge, has resulted in major changes to the aquatic ecology, including increased algal production, increased predation and changes to important food webs (i.e. what eats what).

The response of relevant Government agencies to assessing the possible impacts of the mine-affected water on the riverine biota has been tardy to say the least. The EPA is currently (November 2008) coordinating a comprehensive monitoring and assessment program (water quality, sediments and biota) to determine if there have been adverse effects in the Fitzroy River system due to the mine-affected water.

## ***Agriculture***

It is unlikely that the Ensham mine-affected water has or will cause any major problems for agriculture.

## ***Industry***

### Coal industry

The coal industry is the major industrial user of water in the Fitzroy catchment. Water is used for coal processing, dust suppression, in underground operations and in industrial areas. It is unlikely that water with conductivities to around 1,500 uS/cm would cause any major problems to the coal industry. However, there is evidence that an increase in raw water salinity can lead to increased maintenance costs.

### Stanwell Power Station

The mine-affected water has had no impact on electricity generation activities to date. Additionally, Stanwell Power Station expects to be able to handle likely salinity increases in their raw water over the next month or so, and do not expect any impact on electricity generation.

## ***7.2 Options available to manage these risks***

A number of sensible and feasible management options have been identified by the Technical Working Group (TWG) to address the current water quality problems in the Nogoia-Mackenzie-Fitzroy system. If implemented these management actions will have some positive effect on both drinking water quality and river health, and will show to the community that Government is serious about this issue and prepared to do something positive about it.

However, the ultimate flushing of the mine-affected water currently in the Fitzroy system will only occur with the large flows normally expected in the wet season (December-March).

It should be noted that all the management options currently being considered to alleviate the current water quality problems are restricted to a very large extent by the water use rules (ROP) for the Nogoia-Mackenzie River system, rules that appear to be largely dictated by agricultural and industrial use of the water. These rules may need to be modified in the future to consider other legitimate users of water, such as the environment and townships, and the possible need for a State-owned contingency licence to a certain proportion of the water in Fairbairn Dam.

Option A (to address some of the issues in Bedford and Bingegang Weirs) should be implemented as soon as possible, given the time for water to get from Fairbairn Dam to dilute that in Bedford Weir (3 weeks). Implementation of this Option would have community support in that the Government would be seen to be doing something positive.

Further, it is recommended that the Central Highland Regional Council establish a Task Force to develop a contingency plan for addressing the drinking water quality issue for Blackwater, Bluff, Tieri, Middlemount and Dysart should the Bedford and Bingegang Weirs not be adequately flushed during this coming wet season.

Option C (to address water quality issues in Eden Bann Weir and the Fitzroy Barrage) should be implemented as soon as possible.

Additionally, a contingency plan should be developed by DNRW during November to handle the possibilities that: (a) additional mine-affected water will be flushed into this system from the Isaac/Connors system, and (b) that the expected normal wet season flows will not occur and the dilution and flushing of mine-affected water from Eden Bann Weir and the Fitzroy Barrage does not occur.

An emergency water management plan should be developed by DNRW during November 2008 to improve water quality in the Nogoia-Mackenzie-Fitzroy River system between the storages. This plan will need to be innovative and not constrained by the current restrictive ROP rules.

### **7.3 Review of the EPA-coordinated monitoring & assessment program**

The response of relevant Government agencies to assessing the possible impacts of the mine-affected water on the riverine biota has been tardy, so much so that the Premier, in October 2008, directed the EPA to establish a whole-of-government monitoring program to assess the potential impacts of mine-affected floodwater discharged from the Ensham mine on the Nogoia-Mackenzie-Fitzroy River system.

A draft Project Plan (Fitzroy Basin Water Quality Monitoring: Assessing the impact of Ensham floodwater release, Version 1.0, 28 October 2008) to undertake a comprehensive study of the water quality, sediments and biota in the system has been developed.

This review provided comments to the EPA (29 October 2008) aimed at strengthening the program. A full assessment of the final monitoring and assessment program will be made in a separate report.

Because there is little baseline information available, this study will be challenged in determining if any short-term biological impacts have occurred due to the mine-affected water. For this reason, the study should continue for at least 2 years (3 wet-dry cycles) so that any recovery in the condition of the biota can be measured. The information on the system that will be collected during this time will also be vital in the development of a more comprehensive Fitzroy catchment-wide monitoring and assessment program.

*It is recommended that the EPA include the review comments in revising the draft Project Plan (Fitzroy Basin Water Quality Monitoring: Assessing the impact of Ensham floodwater release), and include a longer timeline for the study (at least 2 years - 3 wet-dry cycles) so that any recovery in the condition of the biota can be measured.*

### **7.4 Assessment of the Government actions to manage the Fitzroy water quality issue**

This current water quality issue in the Nogoia-Mackenzie-Fitzroy River system arose as a result of an emergency situation caused by flooding of the Ensham coal mine in January 2008, the desire by Ensham and Government to get the mine back into production as rapidly as possible, and the decision by the EPA to grant Ensham a Transitional Environmental Program (TEP) to discharge a very large volume (138 GL) of mine-affected water into the Nogoia River.

Given all the factors, the decision by the EPA to issue Ensham with a Transitional Environmental Program for the mine-affected water was justifiable.

However, my assessment is that the EPA process for determining the Ensham TEP was less than adequate (for the reasons outlined in Section 3.4), and that EPA did not adequately consult with key stakeholders in establishing the TEP, or inform the community generally about what was happening and what the possible effects could be. The whole process lacked transparency.

My assessment is that the EPA underestimated the scale of this emergency situation (discharge of a very large volume (138 GL) of mine-affected water over a period of 6-8 months to a river system that was largely not flowing), and as a result misjudged the community reaction to what was happening.

### ***Adequacy of the current Government actions***

Government actions since late August have been mixed in their responsiveness and effect, and include the following:

- Both the CHRC and Queensland Health acted promptly and appropriately when the drinking water quality issue at Blackwater and Tieri became known in late August 2008, and have issued adequate warnings and advice to residents.
- Further, the Rockhampton Regional Council acted swiftly in hosting a multi-agency meeting on 12 September 2008, and in providing adequate warnings and advice to residents, when it became clear that further releases of water from Weirs upstream could compromise drinking water quality in the Rockhampton region.
- The multi-agency meeting, coupled with political representation to the Premier, resulted in the establishment of the Fitzroy River Water Quality Technical Working Group (TWG, 19 September 2008) and my appointment as independent reviewer (14 October 2008).
- The Fitzroy River Water Quality Technical Working Group is chaired by DNRW, with members from EPA, Primary Industries and Fisheries (DPI&F), Queensland Health, Central Highlands Regional Council, Isaac Regional Council, Rockhampton Regional Council, Ensham Resources, Stanwell Corporation, SunWater, Fitzroy Basin Association, Local conservation council and Central Queensland University. The TWG was established *to coordinate the evaluation of key water quality monitoring data within the Fitzroy River system and facilitate interagency communication, collaboration and advice on management strategies to return water quality to normal conditions with an initial focus on the region between Emerald and the Fitzroy Barrage*<sup>28</sup>. They have provided a very informative 'Weekly Update' bulletin since 20 October 2008.
- The EPA are currently (November 2008) coordinating a monitoring and assessment program aimed at assessing the potential impact(s) of mine-affected water discharged from the Ensham coal mine on environmental values (aquatic ecosystems, irrigation, stock watering and drinking water) in the Fitzroy Basin.

---

<sup>28</sup> The specific functions of the TWG are: (a) identify the water quality data that the members are collecting, (b) establish the data sets to focus on for alerting decision makers to water quality concerns, (c) collate data, (d) review/analyse the data, (e) make recommendations based on the review/analysis of the data, including management strategies and any additional monitoring required, (f) communicate data and any recommendations/outcomes within their relevant agencies, including any subsequent public advice, and (g) assist in ensuring a coordinated approach to communication to the community

The somewhat cynical community view of the current Government response to this issue is: (a) that the establishment of the TWG and my review are welcome initiatives but they will be too late to result in any management actions to solve the immediate problem, (b) that the Government is waiting for the wet season rains to 'solve' the problem, and (c) that nothing will be learned from this issue to change Government response processes

While it is true that flushing of the mine-affected water currently in the Fitzroy system will really only occur with the large flows normally expected in the wet season (December-March), the management actions recommended in Section 5 of this report will have some positive effect on both drinking water quality and river health. If initiated, these management actions will show to the community that Government is serious about this issue and prepared to do something positive about it.

The establishment of the TWG has been a very positive move. The TWG has significantly improved the level of knowledge and data sharing, and has provided a forum for sensible discussion about possible management actions.

The EPA-coordinated monitoring and assessment program is also a welcome initiative. However, as noted in the report this would not have been needed if adequate monitoring had been required as part of the Ensham TEP. Also, it is disappointing that it has taken until November for this to have been established when the issue was well appreciated as long ago as late August.

### ***Change needed to manage the Fitzroy water quality situation going forward?***

There appears to be little more the Government can do about this current water quality issue, assuming that decisions are made quickly to initiate the recommended management actions. However, this water quality issue has highlighted a number of broader issues that need to be addressed in the longer term.

#### TEP process

The most obvious is the deficiencies in the TEP process (lack of adequate consultations between the EPA and key stakeholders, lack of transparency in the process, poor communication with the key agencies and the community about the reality of the water quality issue, and what could be done about it). Largely because of the poor communications, but also because of the lack of credible monitoring information, a range of 'conspiracy' theories arose and escalated the issue.

A review of the EPA procedures for developing TEPs has been recommended, with the results (a new set of guidelines) to be published on the EPA web site.

#### Monitoring and assessment

There are a number of monitoring programs being undertaken in the Fitzroy Basin (TWG Document), but it is clear they are largely focused on the specific responsibilities of particular agencies, are not well coordinated, and are not comprehensive.

This review has identified an urgent need for the establishment of comprehensive and well coordinated long-term monitoring and assessment program to assess the ecological health of the Fitzroy River system<sup>29</sup>.

---

<sup>29</sup> DNRW does survey the Fitzroy River system annually through the Statewide Ambient Biological Monitoring and Assessment Program. However, while useful this program based as it is on one biological component of the ecosystem (macroinvertebrates) is far from comprehensive.

### Fitzroy Water Resources Plan

The available options to manage this water quality issue are all severely constrained by the current Fitzroy Water Resource Plan (and operational rules), which has virtually all the water in Fairbairn Dam allocated to consumptive uses, and no contingency allocation owned by the State.

*It is recommended that DNRW consider a more equitable balancing of water between consumptive users and the environment, and the provision of State-owned contingency allocation, during the 10-yearly review of the Fitzroy Water Resource Plan that is currently underway and scheduled to be completed in late 2009.*

### Caretaker of river health

Another important issue that has been highlighted by the current water quality issue is there is no well-defined 'caretaker' of river health in the Fitzroy River catchment, with the legislative authority to adequately protect the aquatic environment. The EPA, DNRW and the Fitzroy Basin Association all appear to have some responsibilities in this regard.

*It is recommended that Government consider the appointment of a 'lead agency' to be the responsible 'caretaker' of river health in the Fitzroy catchment, and for this agency to develop a 'catchment management plan', and a coordinated catchment-wide monitoring and assessment program.*

### Emergency response

It is clear that the Government processes for addressing the current Ensham emergency could be improved. Given the climate change predictions of greater variability in climate over the next 30-50 years, it is certain that similar emergency situations will occur sometime in the future.

*Government should develop a set of Emergency Response Principles relevant to the mining industry to be applied in future situations, such as the current Ensham emergency. The Emergency Response Principles should include the need to: identify a lead agency, undertake a risk assessment, coordinate key agencies, develop an action plan, develop a community communications plan, and identify a key spokesperson.*

## 8. Recommendations

### *Transitional Environment Program Process*

- Rec 1: that EPA undertake a review of the procedures used to develop TEPs and publish the results (a new set of guidelines) on the EPA web site. This review should consider the need for (a) criteria for prioritising the importance of the TEP, (b) undertaking a risk assessment to assist in developing the TEP, (c) a checklist that ensures that all beneficial uses of the receiving waterbody are explicitly considered, (d) a better process for identifying and including key stakeholders in the TEP process, (e) better processes for ensuring the quality of the TEPs developed (e.g. documenting the reasons for various decisions or judgements), and (f) a process for informing the community of the situation associated with potentially controversial TEPs.
- Rec 2: that EPA introduce a process where they undertake random audits of the laboratories being used by mining companies for their ability to adequately sample, process and analyse water quality samples for heavy metals at trace concentrations.

### *Monitoring & assessment*

- Rec 3: that EPA include the review comments in revising the draft Project Plan (Fitzroy Basin Water Quality Monitoring: Assessing the impact of Ensham floodwater release), and include a longer timeline for the study (at least 2 years - 3 wet-dry cycles) so that any recovery in the condition of the biota can be measured.
- Rec 4: that the EFAP surveys to be undertaken by DNRW this coming wet season are expanded to ensure that the effects of the flushing of higher salinity water on fish (and particularly Fitzroy Golden Perch) spawning and recruitment are measured and the implications for future years published.
- Rec 5: that the Biosecurity Queensland study of the 'health' of the fish in weirs be repeated, with other fish species and other storages included, and the study design improved.

### *Management Actions*

- Rec 6: that Option A (to address some of the issues in Bedford and Bengegang Weirs) be implemented immediately, given the time for water to get from Fairbairn Dam to dilute that in Bedford Weir (3 weeks).
- Rec 7: that the Central Highland Regional Council establish a Task Force to develop a contingency plan for addressing the drinking water quality issue for Blackwater, Bluff, Tieri, Middlemount and Dysart should the Bedford and Bengegang Weirs not be adequately flushed during this coming wet season.
- Rec 8: that Option C (to address water quality issues in Eden Bann Weir and the Fitzroy Barrage) be implemented immediately.
- Rec 9: that a contingency plan be developed by DNRW during November to handle the possibilities that: (a) additional mine-affected water will be flushed into this system from the Isaac/Connors system, and (b) that the expected normal wet season flows will not occur and the expected dilution and flushing of mine-affected water from Eden Bann Weir and the Fitzroy Barrage do not occur.

Rec 10: that an emergency water management plan be developed during November 2008 to improve water quality in the Nogoa-Mackenzie-Fitzroy River system between the storages. This plan will need to be innovative and not constrained by the current restrictive ROP rules.

***Fitzroy Water Resource Plan***

Rec 11: that DNRW consider a more equitable balancing of water between consumptive users and the environment, and the provision of State-owned contingency allocation, during the 10-yearly review of the Fitzroy Water Resource Plan that is currently underway and scheduled to be completed in late 2009.

***Caretaker of river health***

Rec 12: that Government consider the appointment of a 'lead agency' to be the responsible 'caretaker' of river health in the Fitzroy catchment, and for this agency to develop a 'catchment management plan', and a coordinated catchment-wide monitoring and assessment program.

***Emergency response***

Rec 13: that Government develop a set of Emergency Response Principles relevant to the mining industry to be applied in future situations, such as the current Ensham emergency.

## **Appendix A: Advantages and disadvantages of the potential management options**

### **A.1 Options for the Mackenzie River Weirs**

#### **Option 1: No intervention – Normal ROP Operational Arrangement**

Under this option there would be no intervention, with weirs drawn down to nominal operating level and water supplied to the townships from the weirs with no further dilution. Releases from Fairbairn Dam will occur under normal operating rules to maintain weir levels at nominal operating level. In summary the Nogoia-Mackenzie Water Supply System would be operated in accordance with current arrangements in the Fitzroy ROP, no specific arrangements would be made to enable additional releases from Fairbairn Dam to create inflows to Bedford Weir, no specific arrangements would be made to enable additional releases from Mackenzie River weirs.

This option includes the previous implemented modifications to town water supply intake works to ensure that better quality water near the surface can be accessed.

Under normal operating arrangements, DNRW do not anticipate that releases from Fairbairn Dam will be required to top up Bedford Weir before the end of the wet season, even without any natural inflows.

#### *Assessment*

This is essentially a 'business as usual' option with the hope for a good wet season.

#### **Option 2: Normal ROP Operational Arrangement (Option 1), except also apply additional release management arrangements for Bedford and Bingegang weirs to manage water quality (this is the Interim Operational Strategy dated 31 October 2008)**

This Option would see the normal ROP operating arrangements for Fairbairn Dam and downstream Weirs applying, and as much of the lower quality water stored at depth in the Weirs as possible released through regulation of flow from the outlet works of Weir storages.

This release strategy applies for releases associated with: (a) topping up downstream storages, and (b) natural inflows that trigger seasonal base flow environmental releases including overflows. Details of this Strategy are contained in the Interim Operational Strategy for the Nogoia Mackenzie Water Supply Scheme - 31 October 2008.

This Option 2 seeks to achieve better water quality in the Weirs than achieved under Option 1, when the opportunity arises. Under low to medium flow conditions, it is anticipated that poorer quality water at depth in the weir storages will persist until there is a larger flushing flow event. Operationally, this Option would aim to (a) scour as much of the poorer quality water in the weirs as possible under normal operating arrangements and low to medium flow conditions, without worsening downstream quality, and (b) reduce the risk of water quality deterioration as the weirs draw down, prior to significant natural flushing flows.

DNRW do not anticipate that releases for topping up downstream storages will be required for several months, as the storages are currently full or near full. Releases associated with small natural inflows are the most likely in the short term. Historically,

by end of December there is about a 36% chance of 30,000 ML natural inflow to Bedford Weir and a 25% chance of 60,000 ML.

#### *Assessment*

This is a sensible and feasible Option. However, if summer rains do not occur it may be necessary to invoke other Options (e.g. Option 2a and Option 4) to ensure the township water supplies do not deteriorate further.

#### ***Option 2a: Same as Option 2, except also apply small scale release from Fairbairn Dam if water quality in weirs worsens to intolerable levels***

This is an extension of Option 2, to provide for the possible situation that the water quality in the weirs worsens to 'intolerable' levels. In this case small releases would be made from Fairbairn Dam to improve the quality of water in the Weirs available to the townships. The releases are much smaller than the releases proposed for Option 3, and are not intended to flush the weirs.

The water available for release is seasonally assigned and is located between Fairbairn Dam wall and the upstream limit of Bedford Weir. Seasonally assigned water is water that is ordered but not used (i.e. is allowed to flow through the system).

#### *Assessment*

This is a sensible and feasible Option. It could be argued that the drinking water currently supplied to Blackwater, Bluff and Tieri is already 'intolerable', and given the 3-7 week time for water to get from Fairbairn Dam to dilute that in Bedford Weir, this should be being planned for now.

#### ***Option 3: Release of water from Fairbairn Dam to flush Mackenzie River weirs***

This Option would see the release of 30,000 to 70,000 ML from Fairbairn Dam (volume required is dependant on the mixing dynamics in Weirs) at about 1,500 ML/day to flush Bedford and Bingegang Weirs. The water available for release is seasonally assigned and is located between Fairbairn Dam wall and the upstream limit of Bedford Weir. Seasonally assigned water is water that is ordered but not used (i.e. is allowed to flow through the system).

If this Option was adopted, the Weirs on the Mackenzie River should be operated in accordance with the arrangements in Option 2.

The Fairbairn Dam is capable of releasing up to 1,500 ML/day, although the flow reaching Bedford Weir will be dependent on upstream consumptive usage. Under the existing ROP rules, Fairbairn Dam only releases water to top up Bedford Weir if this Weir is at or below its nominal operating level. Currently, the level in Bedford Weir is well above this level.

A seasonal assignment arrangement similar to that adopted by Ensham for diluting its releases would be required to implement this Option. Assuming the market price for seasonal assignment water in this system is say \$100 per ML, a volume of 30,000 ML would cost about \$3 million, although the actual cost will depend on market forces, including the presence of willing sellers.

### *Assessment*

At this stage it does not seem that Option is feasible. I understand that the maximum amount that could be seasonal assigned into the Bedford Weir pond within the current ROP rules is in the order of 3,450 ML. It would therefore require considerable expenditure to secure the 30,000-70,000 ML required.

However, this Option should remain as a contingency Option should the wet season rains be less than required, and be re-evaluate (against the trucking and desalination Options (5 and 6) if needed in March 2009

### ***Option 4: Pump poorer quality water from Bedford Weir and store in private farm dams for later use or release back when flows are higher***

This option involves pumping poorer quality water out of Bedford Weir into nearby farm dams. There is a 5,400 ML storage adjacent to Bedford Weir, which is currently empty. If Option 4 was implemented, this would need to be coupled with (a) Option 2 and wait for natural inflows, or (b) Option 3 with release of water from Fairbairn Dam to top up Mackenzie River Weirs and improve water quality.

Although pump and diversion works have been installed at Bedford Weir, only small pump capacity (45 ML/day) is understood to be currently operational. Other works capable of 450 ML/day are currently not operational.

Water pumped out of Bedford Weir would need to be seasonally assigned. Assuming the market price for seasonal assignment water in this system is say \$100 per ML, 5,000 ML will cost about \$0.5 million.

While the Fitzroy ROP provides for seasonal assignment into the Bedford Weir pond, as at 23 October 2008, the maximum amount that could be seasonal assigned into the Bedford Weir pond within the ROP rules is in the order of 3,450 ML.

### *Assessment*

This is a sensible and feasible Option. It is also the preferred option of the Central Highland Regional Council, the authority responsible for providing safe and palatable drinking water to the communities of Blackwater, Bluff and Tieri.

The main objections to this Option appear to be the result of the rather restrictive water use rules for this Nogoia-Mackenzie River system, rules that appear to be largely dictated by agricultural and industrial use of the water. These rules may need to be modified in the future.

However, given the current situation of less than adequate drinking water for the three towns in question, it is recommended that this option be further developed during November 2008 and implemented as soon as possible. Implementation of this option would have community support in that the Government would be seen to be doing something positive

## ***A.2 Options for town water supplies***

### ***Option 5a: Trucking 'drinking' water supply supplies***

This option considers supplementing the supply to Middlemount, Dysart, Blackwater, Bluff and Tieri from Bedford and Bingegang Weirs with an additional 'drinking' water supply trucked from another nearby town's water supply

Dysart and Middlemount currently obtain their town water supplies from Bingegang Weir, while Blackwater, Bluff and Tieri obtain their water supplies from Bedford Weir. The Emerald Town Water Supply is not affected by the poorer quality water currently affecting Bedford Weir and Bingegang Weir.

The cost to truck water from Emerald at a rate of 10 litre/person/day to Dysart, Middlemount, Tieri and Blackwater (total population 11,700) has been estimated be around \$100,000 per month. Some temporary storage infrastructure would also need to be installed to store the trucked water (not connected to town water supply network).

#### *Assessment*

This is a sensible and feasible Option that could be implemented rapidly if the water quality in the two Weirs deteriorates further. Obviously funding would have to be found to implement this Option. It is recommended that this option be part of a contingency plan should the water quality deteriorate further.

#### **Option 5b: Mobile desalination plant**

This Option would involve installation of a mobile desalination plant to supply either: (a) supplemented 'drinking' water only (would require residents to collect the water), or (b) desalinated town water through the existing town reticulation system.

Desalination plants to provide an output of about 100 kilolitre/day (or equivalent to about 9 litre/person/day for the total populations of Dysart, Middlemount, Tieri and Blackwater) are available and multiple units of this capacity can increase the capacity. The combined lease, operation and maintenance cost for such a plant would be about \$20,000 per month. Company's that set up these plants can monitor the plants performance remotely and will provide technical backup advice if required.

For comparative purposes, a reverse osmosis desalination plant providing an output of about 1.5 ML/day (1,500 kilolitre /day or equivalent to 130 litre/person/day for the total populations of Dysart, Middlemount, Tieri and Blackwater) would cost about \$100,000 per month (\$66,000 per month leasing plus \$30,000 per month operation and maintenance) plus the cost of brine disposal. Such plants are available commercially, generally in a transportable container and are used for mining and construction camps.

#### *Assessment*

This is a sensible and feasible Option. Obviously funding would have to be found to implement this Option. It is recommended that this option be part of a contingency plan should the water quality deteriorate further.

#### **Option 5c: Other Town Water Supply Options**

A number of pipeline options have been considered, including: (a) extension of Gregory Pipeline to Tieri, (b) extension of Burdekin to Moranbah Pipeline to Tieri, (c) extension of Pipeline from German Creek Mine to Tieri, and (d) reverse flow reticulation system to supply these towns from either the Eungella pipelines or the Burdekin/Moranbah pipeline.

Generally, these options involve the extension of existing pipelines, which involves major capital expenditure and a delay for procurement and construction. By their nature such works are permanent capital works.

The existing pipelines generally deliver untreated water, and to supply the townships with drinking water, the raw water could be delivered to the existing water treatment plants in each town, treated and reticulated through the town.

An alternative to supplying the whole town water supply from these pipelines, would be to supply a supplemented 'drinking' water supply only to the towns, requiring lower capacity pipelines which could be installed at a significantly lower cost. Such an arrangement might require a new low capacity treatment plant to be installed in each town. Alternatively, the raw water might be stored to allow the treatment plant to operate for periods at its minimum capacity. Storage of this treated water stored then allows residents to collect this drinking water from distribution points.

Complications arise from the need to treat this drinking water and keep it separate from the existing town water supply networks that continue to treat and supply the poorer quality water for purposes other than drinking.

#### *Assessment*

This is not a feasible Option at this stage. Preliminary cost estimates suggest that extensions of existing pipes, even for drinking water supply only, is cost prohibitive compared to other options as a solution to this temporary problem.

### **A.3 Options for the lower Fitzroy and the Fitzroy Barrage**

#### ***Option 6a: No intervention – normal ROP operational arrangements***

Under this Option, the Lower Fitzroy and Fitzroy Barrage water supply schemes would be operated in accordance with arrangements in the Fitzroy ROP. In summary, each storage supplies consumptive water from its pond, Eden Bann Weir would supply the reach upstream of the Fitzroy Barrage pond by releases, and when the Fitzroy Barrage falls to its nominal operating level (0.4 metres below full supply level), releases would be made from Eden Bann Weir to maintain the level in the Fitzroy Barrage at its nominal operating level.

The water quality in Eden Bann Weir and the Fitzroy Barrage, while elevated compared to normal water quality levels, has been and remains considerably better than the quality in the Mackenzie River Weirs.

Monitoring of water quality in Eden Bann Weir and Fitzroy Barrage has indicated that the water quality is highly variable throughout both storages.

#### *Assessment*

This is essentially a 'business as usual' option with the hope for a good wet season.

#### ***Option 6b: Same as Option 6a, except apply additional release management arrangements for Eden Bann Weir (the Interim Operational Strategy dated 31 October 2008)***

This Option aims to achieve better water quality at the intake works for Rockhampton Regional Council and Stanwell Power Station than would be achieved under Option 1 if the opportunity arises. Implementation of this option may result in operation outside ROP rules

Under this Option, normal ROP operating arrangements for Eden Bann Weir and the Fitzroy Barrage would apply, except where it is otherwise determined that a release: (a) should be delayed because it was likely that it would worsen the quality of water

at the Rockhampton Regional Council and Stanwell Power Station intakes, or (b) should occur because it was likely that the release would improve the quality of water at the Rockhampton City Council and Stanwell Power Station intakes. The strategy details are contained in the Interim Operational Strategy for the Lower Fitzroy and Fitzroy Barrage water supply schemes dated 28 October 2008.

The water quality in Eden Bann Weir and the Fitzroy Barrage, while elevated compared to normal water quality levels, has been and remains considerably better than the quality in the Mackenzie River Weirs. However, it appears that there has been no consideration of other possibilities that could result in more mine-affected water from upstream being flushed into Eden Bann Weir and the Fitzroy Barrage, for example a small flow event in the Isaac/Connors system could flush mine-affected water reportedly in that system (S. Christensen, Personal Communication, October 2008) into Tartrus Weir, and then flush this water plus the mine-affected water current in Tartrus Weir further downstream.

Based on historical data there is a quite reasonable probability that large natural flows will occur in this system. For example, by end of December there is about a 50% chance of in excess of 122 GL natural inflow to Eden Bann Weir<sup>30</sup>, a 75% chance of 162 GL by end of January, and 75% chance of about 440 GL by end of February.

#### *Assessment*

This is a sensible and feasible Option, and should be adopted. Additionally, I recommend that a contingency plan be developed during November to handle the possibilities that: (a) additional mine-affected water will be flushed into this system from the Isaac/Connors system, and (b) that the expected normal wet season flows will not occur and the dilution and flushing of mine-affected water from Eden Bann Weir and the Fitzroy Barrage does not occur.

#### ***Option 6c: Release of water from Fairbairn Dam to improve water quality in Eden Bann Weir and Fitzroy Barrage***

This Option would involve the release between 150 GL and 250 G of waterL from Fairbairn Dam (at about 1,500 ML/day) to flush mine-affected water from Eden Bann Weir and the Fitzroy Barrage. It should be noted that this water is seasonally assigned (i.e. ordered but not taken up by irrigators) and would be located between Fairbairn Dam wall and the upstream limit of Bedford Weir.

If this Option was adopted, Eden Bann Weir should also be operated in accordance with the arrangements in Option 6b above.

DNRW Rockhampton have assessed that this Option is unlikely to significantly improve the quality of water in Eden Bann Weir for the following reasons: (a) Fairbairn Dam is only capable of releasing a maximum of 1,500 ML/day, with the flow reaching Bedford Weir and downstream Weirs dependent upon upstream consumptive usage and the state of downstream storages and waterholes, (b) the volume required to flush Eden Bann Weir and the Fitzroy Barrage will be dependant on the mixing dynamics in these storages, but could be in excess of 200 GL<sup>31</sup>, (c) the release of 100 GL at 1,500 ML/day will take more than 2 months (mid January),

<sup>30</sup> Note – Eden Bann Weir retains a volume of 40 GL at full supply level.

<sup>31</sup> The capacity of Bedford, Binegang, Tartrus and Eden Bann weirs plus waterholes is estimated to be approximately 110 GL, and with the Fitzroy Barrage the total volume is in excess of 190 GL.

while the release of 200 GL will take more than 4 months (mid March), and (d) it is probable based on historical records that significant natural inflows would have occurred by the end of February.

A seasonal assignment arrangement similar to that adopted by Ensham for diluting its releases would be required. The cost of 200 GL of water has been estimated to be in excess of \$20 million. Additionally, removal of 200 GL of water from Fairbairn Dam would mean significantly less water for farmers around Emerald with considerable socio-economic impacts on the Emerald and surrounding communities.

#### *Assessment*

This is not a feasible Option at this stage given: (a) the time for water to travel from Fairbairn dam to Eden Bann Weir and the Fitzroy Barrage, (b) the cost to purchase the water, and (c) the reasonable probability that the impending wet season flows will flush the system. However, this Option should remain as a contingency Option should the wet season rains be less than required to flush the storages, particularly given that if this occurs the large Rockhampton community will face the prospect of drinking water that is less than adequate.

## Appendix A: Advantages and disadvantages of the potential management options\*

<b>Option</b>	<b>Identifier</b>	<b>10. Advantages</b>	<b>Disadvantages</b>
1	No intervention – Normal Resource Operation Plan (ROP) arrangements	<ul style="list-style-type: none"> <li>• In accordance with the ROP</li> <li>• No impact on water entitlement security</li> <li>• Low cost</li> </ul>	<ul style="list-style-type: none"> <li>• Requires a significant natural flow event for flush weirs and make a difference</li> <li>• If no natural inflows occur, the stored water quality will deteriorate as the better quality surface waters are drawn off for consumptive purposes and through evaporation</li> <li>• Water will not be released from Fairbairn Dam to top up Bedford Weir before end of wet season, even without any natural inflows</li> </ul>
2	Option 1, with additional release management arrangements for Bedford and Bingegang Weirs to manage water quality (the Interim Operational Strategy 31 October 2008)	<ul style="list-style-type: none"> <li>• In accordance with the ROP</li> <li>• No impact on water entitlement security</li> <li>• Low cost – only requires some additional operational and monitoring effort</li> <li>• Improved stored water quality for small to medium flow events in the short term</li> <li>• Limits downstream progression of poorer water quality</li> </ul>	<ul style="list-style-type: none"> <li>• Requires a significant natural flow event for flush weirs and make a difference</li> <li>• If no natural inflows occur, stored water quality will deteriorate as the better quality surface waters are drawn off for consumptive purposes and through evaporation</li> </ul>
2a	Option 2, with small scale release from Fairbairn Dam if water quality in weirs worsens to intolerable levels	<ul style="list-style-type: none"> <li>• If water quality worsens to ‘intolerable’ levels, will improve quality of water available to towns</li> <li>• Delays need to secure seasonal assignment water compared to option 3, therefore increased opportunity for natural flows to improve water quality</li> <li>• Small volume of seasonal assignment water may be easier to secure than larger volume for Option 3</li> <li>• High cost if needed, but likely to be lower than cost for large flushing release under Option 3, because of delayed need for releases and therefore increased opportunity for natural</li> </ul>	<ul style="list-style-type: none"> <li>• Preparatory planning required to establish level at which water quality is ‘intolerable’</li> <li>• Uncertainty over volume and rate of releases</li> <li>• Increasing public concern as water quality worsens to intolerable levels</li> </ul>

		flows to flush without need for releases, and cost of seasonal assignment likely to be lower because of smaller volume sought	
3	Release of water from Fairbairn Dam to flush Mackenzie River weirs	<ul style="list-style-type: none"> <li>• May make substantial improvement to water quality in Bedford and Bingegang Weirs within 3-7 weeks of commencement of releases (time depends on mixing dynamics)</li> <li>• Will improve quality of water at town water supply intakes</li> </ul>	<ul style="list-style-type: none"> <li>• Quantity of water required to be seasonally assigned is not certain because of the uncertainty re mixing dynamic. This uncertainty is lessened by the release of poorer quality water through the weir outlets as part of this option</li> <li>• Water released will not be available for productive use (e.g. irrigation etc) in Nogoia system – potential socio economic impacts on Emerald community</li> <li>• Poorer quality water currently in Bedford and Bingegang Weirs will be flushed downstream</li> <li>• Need for willing sellers in market already subject to previous seasonal assignment</li> <li>• High cost</li> <li>• Reasonable prospects of natural inflows to Bedford by January 2009, making release of water from Fairbairn Dam unnecessary</li> <li>• Probability of substantial inflows into Fairbairn to 'replace' the released water is much less than at locations further downstream.</li> </ul>
4	Pump poorer quality water out of Bedford Weir and store water in private farm dams for use by owner(s) of these dams	<ul style="list-style-type: none"> <li>• Will achieve more rapid water quality improvement in the weirs than natural inflows into a full storage or releasing to a full storage</li> <li>• The pumped water may be able to be productively used (from the farm dam)</li> <li>• Would removal of some of the poorer quality water from the Mackenzie River, reduce the extent of poorer quality water passing downstream</li> </ul>	<ul style="list-style-type: none"> <li>• Will require securing arrangements with owner of farm dam(s), and securing seasonal assigned water in market that has already experienced seasonal assignment of water</li> <li>• High cost</li> <li>• ROP may limit extent that this option may be implemented</li> <li>• Reasonable prospects of natural inflows to Bedford by January 2009 in which case pumping water out of the storage not needed</li> </ul>
5a	Trucking 'drinking' water supply supplies	<ul style="list-style-type: none"> <li>• Low cost Option (relative to other options) that</li> </ul>	<ul style="list-style-type: none"> <li>• Possible adverse public perception</li> </ul>

		<p>can be easily terminated when water supplies return to normal</p> <ul style="list-style-type: none"> <li>• Low capital cost – preliminary estimate of cost of storage facilities might be in range of \$100,000 to \$200,000</li> <li>• If water quality deteriorates in any town and can't be used for drinking, supplies can be obtained quickly</li> <li>• Reduces urgency to address water quality in Bedford and Binegang Weir</li> </ul>	<ul style="list-style-type: none"> <li>• Residents would need to collect water from distribution points in town rather than having water delivered to homes</li> </ul>
5b	Mobile desalination plant	<ul style="list-style-type: none"> <li>• Desalination plants can be leased until no longer required</li> <li>• Cost is comparable to cost of trucking water and lower than other options</li> </ul>	<ul style="list-style-type: none"> <li>▪ For drinking water not connected to town water supply network, likely that temporary storage infrastructure needed to store the desalinated water</li> <li>▪ For drinking water, residents would need to collect water from distribution points in town rather than having water reticulated to homes.</li> <li>▪ Requirements in relation to disposal of brine</li> </ul>
5c	Other Town Water Supply Options	<ul style="list-style-type: none"> <li>• Provides an alternative/additional supply if future water supply and water quality problems occur</li> </ul>	<ul style="list-style-type: none"> <li>• Very high cost of extending existing major pipelines</li> <li>• Uncertainty with availability of water allocations at critical periods</li> <li>• For low capacity drinking water supply pipelines, method of treating alternate raw water sources not clear</li> <li>• Potential to contaminate supplemented drinking water if use existing treatment works to treat both supplemented drinking water from alternate source and a larger volume of raw poorer quality water for purposes other than drinking</li> </ul>
6a	No intervention – normal ROP operational arrangements	<ul style="list-style-type: none"> <li>• In accordance with the Resource Operation Plan.</li> <li>• No impact on water entitlement security.</li> <li>• Low cost.</li> <li>• High probability of significant natural flow event by January</li> </ul>	<ul style="list-style-type: none"> <li>• Water quality continues to deteriorate, affecting town water supplies</li> <li>• A significant natural flow event required for significant flushing of Eden Bann Weir and Fitzroy Barrage.</li> </ul> <p>If no natural inflows occur, stored water quality will</p>

6b	Option 2, except apply additional release management arrangements for Eden Bann Weir (the Interim Operational Strategy 31 October 2008)	<ul style="list-style-type: none"> <li>• No impact on water entitlement security.</li> <li>• Low cost – only requires some additional operational and monitoring effort.</li> <li>• Potential improved water quality at the Rockhampton Regional Council and Stanwell Power Station intakes if opportunity presents.</li> <li>• High probability of significant natural flow event by January.</li> </ul>	<p>deteriorate through evaporation.</p> <ul style="list-style-type: none"> <li>• A significant natural flow event required for significant flushing of Eden Bann Weir and Fitzroy Barrage.</li> </ul> <p>If no natural inflows occur, stored water quality will deteriorate through evaporation.</p>
6c	Release of water from Fairbairn Dam to improve water quality in Eden BannWeir and Fitzroy Barrage	<ul style="list-style-type: none"> <li>▪ May improve quality of water in Eden Bann Weir and Fitzroy Barrage in 4 to 5 months if wet season essentially fails. BOM forecasting suggests failure of wet season unlikely at this time.</li> </ul>	<ul style="list-style-type: none"> <li>▪ The quantity of water required to be seasonally assigned is substantial and would be expected to have a significant impact on production in the Nogoia Mackenzie system -potential socio economic impacts on Emerald community</li> <li>▪ Extremely unlikely required volume will be available for seasonal assignment</li> <li>▪ Need for willing sellers, in market already subject to previous seasonal assignment</li> <li>▪ Very high cost</li> <li>▪ Good prospects of natural inflows to Eden Bann Weir by January 2009, and release of water from Fairbairn Dam not needed/not beneficial</li> <li>▪ Probability of necessary substantial inflows into Fairbairn to “replace” released water much less than at locations further downstream.</li> <li>▪ Poorer quality water stored in Bedford and Bingegang weirs passes downstream - may be an initial worsening of water quality before any improvements</li> </ul>

### 2.10 – Mine industry incidents

*Procedural guides further define complex decision-making processes or requirements of the Department of Environment and Resource Management. Procedural guides provide guidance and information to assist staff in the completion of specific tasks or in making certain judgments. Procedural guides are for internal use only.*

#### **Purpose and scope**

This document guides DERM personnel on the issues, responsibilities and roles in responding to releases of hazardous and toxic materials such as chemicals and wastes from mine sites to places where they may cause environmental harm.

#### **Background**

Mine activities often involve the use of large quantities of hazardous materials such as explosives and mineral processing chemicals, as well as large volumes of wastes in the form of waste rock, tailings, process water or air emissions that contain hazardous materials. The consequences of releases of these potentially hazardous materials as a result of accidents, process failures or extreme weather events can range from minimal to severe depending on the toxicity and quantity of materials released and site specific circumstances such as proximity of residents, environmental values affected and dilution in the atmosphere and waterways.

While many mine sites are located in remote area with minimal immediate risk to high density populations, they are often adjacent to waterways where releases may pose a risk to downstream ecological values and catchment uses over very large areas. Impacts may include: contamination of land and waters; acute and chronic toxic effects to biota and productivity of plants, fish, animals (including livestock) and birds; and public health risks such as contaminated drinking water, fires, explosions, and fumes.

Mine sites operate under environmental authorities with conditions that may include stated measures for carrying out the activity and any authorised levels of releases. Mine sites must have appropriate emergency response and recovery plans relevant to the specific risks for the site and the adjacent environment. Site owners are responsible for these incident plans, responses and clean up activities for any associated pollution incidents.

The extent of the impacts from mine site releases will depend on a range of factors including the contaminant type, release quantity, the area of impact, the rate of the release and site specific circumstances such as the proximity of sensitive environmental values, populated areas, seasonal conditions, level of dilution in water bodies and the capacity of the environment to absorb impacts.

Contaminants of concern can include:

- Process chemicals (e.g. cyanide residues)
- Acid mine drainage (e.g. from mine pits or waste dumps or tailings dams)
- Saline waters (e.g. salty, sulphate or mineral rich waters)
- Mineral releases (e.g. heavy metals leaching or controlled or uncontrolled releases)
- Bulk sediments (e.g. fines from coal washing or tailings or site erosion)
- Explosives (e.g. large volumes of ammonium nitrate)

This procedure is intended to cover mine site releases of short duration and acute impacts that require immediate response action and are not intended to cover chronic releases even though they may be related to an initial acute incident.

Releases can be in the form of a specific incident such as spills, a dam failure or protracted discharges due to prolonged wet weather causing over-topping of containment structures. All releases to waters should be considered as having the potential for adverse impacts given the sensitivities of aquatic ecosystems and downstream water users.

## Procedure

### Initial Incident Classification

The following initial classifications are to be used as a general indication only. Specific determination of the incident classification level will be determined on a case-by-case basis considering:

- Specific contaminant toxicity and reactivity
- Amount/volume of release
- Proximity to populated areas
- Proximity, size, value and sensitivity of adjacent environmental areas (considering habitat type, area at risk, threatened species, downstream users, etc)
- Mitigating factors (e.g. seasonal conditions or dilution)
- Rate of the release (e.g. short intense slug or spread over time)
- Extent of area impacted
- Pathways for spill to enter a waterway or an area where the public may be exposed.

The following thresholds can be used as an *initial guide* to classifying incidents.

<b>Minor Incident</b>
Release to land of small quantities of low-risk chemicals, explosives, flammable or hazardous materials on or beyond the boundaries of the mine site, with no release to a waterway
Release to waterways of small quantities or low concentrations of contaminants for a short period that are unlikely to cause acute harm in the adjacent environment and will have no discernable effects on overall or downstream water quality or use

<b>Medium Incident</b>
Release to land of moderate quantities or concentrations of contaminants on or beyond the boundaries of the mine site that may cause acute or long-term environmental harm.
Release or potential release to a waterway of moderate quantities or concentrations of contaminants that may cause acute harm in the adjacent environment and may have an effect on downstream water quality and use. Contaminants may include chemicals, explosives, flammable or hazardous materials.

<b>Major Incident</b>
Release to land of large quantities or concentrations of contaminants on or beyond the boundaries of the mine site that may cause wide-spread environmental harm.
Release to waterway of large quantities or concentrations of contaminants that are expected to cause acute harm in the adjacent environment and will have an effect on downstream water quality. Contaminants may include chemicals, explosives, flammable or hazardous materials.

## Actions

### **Minor Incidents - Business Hours & After Hours**

- Regions to manage any response requirements.
- Responses only during normal business hours.
- Contact mine site/manager directly.

- All reasonable measures need to be taken to minimise the release of contaminants.
- Mine site/manager will need to provide incident notification reports.
- Regional staff may attend as is appropriate.
- Regional Managers can escalate Minor incidents to a Medium classification based on environmental risk matrix assessment.
- DERM to provide advice on minimising environmental harm generally.
- All incidents to be recorded.

## **Medium Incidents**

### Business Hours

- Regions to manage any response requirements.
- Regional staff to be mobilised and attend as required.
- Regional may contact SIRN for technical support and direction.
- Contact mine site/manager to arrange a response.
- All reasonable measures need to be taken to minimise the release of contaminants.
- DERM to provide advice on minimising environmental harm generally.
- All incidents to be recorded.
- Regional Manager to be advised and brief upwards as appropriate.

### After Hours

- SIRN to manage initial assessment and decide on any response requirements.
- Regional staff to be mobilised and attend as recommended by SIRN (24 hour response capacity may be required).
- Contact mine site/manager directly to arrange a response.
- Regional staff to act as field support for SIRN with technical support and direction from SIRN.
- Regional Manager to be advised and brief upwards as appropriate.
- All reasonable measures need to be taken to minimise the release of contaminants.
- DERM to provide advice on minimising environmental harm generally.
- All incidents to be recorded.

## **Major Incidents**

### Business Hours & After Hours

- Incident Response Unit (IRU) to manage initial assessment and decide on any response requirements within the constraints of any disaster or safety declarations.
- SIRN staff to be mobilised on site to manage DERM response (24 hour response capacity required).
- Regional staff may be mobilised and attend to bridge time required for IRU/SIRN to attend (24 hour response capacity may be required).
- Contact mine site/manager directly to arrange a response.
- Regional staff to act as field support for SIRN with technical support and direction from SIRN.
- Regional Manager to be advised and brief upwards as appropriate.
- All reasonable measures need to be taken to minimise the release of contaminants.
- DERM to provide advice on minimising environmental harm generally.
- All incidents to be recorded.

## Issues to consider

### Tactical Options

1. Confirm MSDS information considering:
  - Safety warnings;
  - PPE requirements;
  - Reactivity Alerts and Profiles;
  - Air and Water Reactions;
  - Health Hazards from fumes and contact;
  - Response Recommendations:
    - Fire Fighting;
    - Containment, neutralising and cleanup;
    - First Aid;
  - Disposal requirements.
2. Identify environmental threat considering:
  - Proximity to human communities;
  - Habitat type;
  - Size/area of habitat at risk;
  - Sensitivity of the area to threat;
  - Listed threatened status of habitat;
  - Wildlife species at risk;
  - Wildlife numbers at risk;
  - Wildlife diversity at risk;
  - Threatened status of wildlife;
  - Environmental toxicity issues;
  - Potential for impacts on downstream water supply / beneficial uses.
3. Response options:
  - Secure area;
  - Stop or minimise the flow or escape of material from primary source;
  - Minimise or stop the movement of contaminants by appropriate containment;
  - Look at soaking up contaminants with sand, earth, cement or other absorbents;
  - Construct earthen bunds in catchments as primary and secondary containment options;
  - Implement other containment devices (e.g. booms);
  - Use vacuum trucks and tip trucks to remove contaminants;
  - Look at dilution and neutralisation options;
  - Minimise mixing of contaminants with other reactive sources;
  - Minimise generation of excess contaminated soil or water;
  - Manage fire and fire risks;
  - Consider burning as a disposal option.
4. Contact the owner of the site or transport company for a copy of their emergency response plan.
5. Notify compliance investigators.
6. Request sampling activity for evidence and recovery purposes.
7. Internal Agency briefings (potentially) include:
  - Office of Water Supply Regulator, Water authorities and Users
  - Regional Manager (Regional Service Delivery and QPWS)
  - Regional Service Director (Regional Service Delivery and QPWS)
  - State Compliance Unit
  - Assistant Director-General (Regional Service Delivery and QPWS)
  - Media Unit
  - Director Generals Office
  - Minister's Office
  - Premier's Office

- State Disaster Management Group
  - Contaminated Lands Unit
  - Petroleum and Gas Group
  - Regulated Dams Group
8. External agency briefings (potentially) include:
- Emergency Services
    - Qld Fire and Rescue Service
    - Queensland Police Service
    - Queensland Ambulance Service
    - Emergency Management Queensland
  - Local Authorities
  - Water supply authorities
  - Downstream water users / stakeholders
  - Qld Health
  - Biosecurity Queensland
  - Transport and Main Roads
  - Mines and Energy
  - Maritime Safety Queensland
  - Great Barrier Reef Marine Park Authority
  - Australian Maritime Safety Authority
9. Private industry support for:
- Waste transport
  - Waste storage
  - Waste treatment
  - Response support

### **Roles and Responsibilities**

#### **DERM**

Provides advice and support on environmental protection issues; risk assessment; cleanup; recovery and waste disposal.

- Ensure that cleanup is to an appropriate standard.
- Provide regulatory oversight and supervision as necessary.
- Compliance role including evidence collection as necessary.
- Ensure a proper transition from the initial emergency response phase to the longer-term recovery phase (administered by the Region) including management of acute and chronic impacts.
- Ensure that recovery phase planning and implementation occurs in accordance with the documented *Policy principles - mining industry incidents*.

#### **QPWS**

- Response combat support as determined on a case-by-case basis.
- Provide flora and fauna advice for impacted areas.

#### **Office of Water Supply Regulator, Water authorities and Users**

Where there is the potential for contaminants to adversely affect public drinking water supplies, for both surface and groundwater situations, the Office of Water Supply Regulator and relevant water authorities and users should be contacted.

- Office of Water Supply Regulator, in conjunction with Queensland Health, may provide; public health advice and direction, interpretation of laboratory results and advice on safe levels of contaminants.
- Water supply authorities are responsible for water impoundments, water treatment and supply.
- Stakeholders within the likely affected downstream areas should be notified of the incident and advised the necessary precautionary actions to take.

---

### Qld Police Service (QPS)

Where the *Public Safety Preservation Act* has been declared the responsibilities of the QPS are to provide:

- Control and coordination of the incident (including the on-site and off-site emergency environment);
- Coordination of the efforts of contributory agencies;
- Securing the incident scene from unauthorised entry or departure;
- Crowd and traffic control.

Additional Police responsibilities include:

- Establish and maintain Police Forward Command Post (PFCP) including the media centre;
- Security support for Queensland Ambulance Service casualty collection, treatment and transport loading areas;
- Facilitating resource supply through State Crisis Centre (when applicable);
- The rendering safe of explosive devices;
- Establishing registration of evacuees;
- Establishing victim registration both deceased and alive;
- Controlling entry/egress points from the cold zone and outer cordon;
- Staging and marshalling areas off-site for supporting agencies and resources;
- Coordination of public protection strategies including evacuation and adjacent refuge;
- Liaison with QFRS/QAS/QH (at on and off-site locations);
- Evidence security – where criminal or negligence origins are evident;
- Engaging with the Media in concert with the QFRS Incident Controller.

### Queensland Fire & Rescue Service (QFRS)

QFRS has lead responsibility for protection of persons, property and the environment from fire and hazardous materials emergencies. It also provides an advisory service, and other measures to promote safety and protect property if a fire or hazardous materials emergency happens.

The QFRS will act as the lead Chemical/HazMat combat agency and will:

- Identify, contain and mitigate the hazard;
- Identify Chemical/HazMat operating zones for the safety of personnel including those of other agencies;
- Rescue and decontamination of persons who are not fully ambulant and are known to be contaminated;
- Engage with the media in liaison with the Police Forward Commander.

Additional QFRS responsibilities may include:

- Establish and maintain incident hot/warm/cold zones with controlled entry/egress points;
- Maintain appropriate Chemical/HazMat Control Procedures;
- Identify and tag contaminated articles including clothing;
- Decontaminate incident personnel and the public;
- Assist in off-site decontamination where possible;
- Control entry operations within the hot zone such as rescue and identification;
- Provide a Liaison Officer to interact with the Police Forward Command Post;
- Provide Chemical/HazMat assistance to other responding agencies where biological or radiological hazards are present.

The QFRS HazMat function is supported by the Response Advice to Chemical Emergencies (RACE) team. RACE support includes:

- An expert mobile advisory service on and off site in respect to chemical incidents;
- Specialist training for emergency services for response to Chemical/HazMat Incidents;
- Carrying out on-site tests to determine the type, concentration and distribution of the hazardous substance involved;
- Providing expert advice to the QFRS Controller and QAS Commander and liaison with Qld Health in respect to determining the threat from the particular hazard;
- Providing information and advice to the QFRS Controller and the Police Forward Commander and the QAS Commander, about Chemical/HazMat implications for management of the incident. This advice may be about the degree of threat from the hazard, the location and dimensions of the spread of the hazard and assistance in establishing Chemical/HazMat Control Zones and Public Protection Strategies;
- Sample management that may include retrieval and liaison with Qld Health and other agencies.

### **Queensland Ambulance Service (QAS)**

QAS is responsible for on site medical care in consultation with Qld Health including establishment of casualty collection, triage, treatment and assessment areas and transportation of patients to appropriate health facilities. Additional Responsibilities include:

- Maintain casualty collection, triage and treatment areas;
- Establish and maintain ambulance transport area;
- Establish the casualty collection post adjacent to the decontamination corridor exit (on advice from the QFRS Controller);
- Establish the casualty triage and treatment areas at a distance, which will provide optimum protection to casualties and personnel (on advice from the QFRS Controller);
- Provide a Liaison Officer to the Police Forward Command Post;
- Estimate and obtain on and off-site medical and health resources as required;
- Notify Multi-Casualty Incidents (MCI) to Queensland Health.

### **Queensland Health (QH)**

QH provides public health advice and direction including advice to the Medical and Ambulance Commanders on the clinical management of casualties as well as:

- Hospital or other health facility casualty response as required;
- On-site medical team support in consultation with Ambulance Commander;
- Off-site laboratory analysis of materials, including biological samples;
- Advice on decontamination.

### **Biosecurity Queensland**

Biosecurity Queensland is the lead combat agency for emergency animal and plant diseases that occur in Queensland. Biosecurity may become involved in a mine site release incident when:

- The release of a pollutant may destroy or render livestock or agricultural products unsafe for use as food for humans or other livestock;
- The release of a pollutant may destroy, damage or render unusable land or waters that are used for farming or fishing related purposes;

Any of the above situations can present a serious threat to the food chain and the natural environment and are guided under arrangements outlined in the *Queensland Veterinary Emergency Plan*.

Biosecurity may provide; advice and direction on agricultural issues, interpretation of laboratory results and advice on safe levels of contaminants.

### **Mines and Energy (M&E)**

The M&E Gas Examiner's duties as outlined under the *Petroleum & Gas Act, 2004* and the Explosives Inspectorate as outlined in the *Explosives Act, 1999*. M&E provide safety advice in the areas of explosives, petroleum and gas related incidents including providing advice on explosives issues ranging from commercial high explosives to pyrotechnics and fireworks plus advice on incidents relating to oil production and those involving natural or LP gas.

### **State Emergency Services (SES)**

The SES is a volunteer based organisation providing response personnel support. SES is mobilised by the Department of Emergency Services in times of general emergencies and disasters.

### **Qld Transport (road)**

- May be contacted during incidents;
- Formal requirements and contact systems to be finalised.

### **Local Authorities**

- Councils may need to be contacted also to clean up small amounts of pollutants or be advised of water quality issues that may affect water supply and other beneficial uses.

### **Utility Companies**

- May need to be contacted also to be advised of water quality issues that may affect water supply and other beneficial uses.

### **Mine Site Owners**

- Responsible for contacting those who may be impacted;
- Responsible for clean up costs and arrangements;
- Responsible for meeting conditions of environmental authorities and general environmental duty;
- Responsible for meeting the requirements of any orders and any ongoing monitoring.

### **Industry Support/Contractors**

- Waste Transport
- Waste Storage
- Waste Treatment
- Response Support

### **Contacts**

Refer to Procedural Guides for Environmental Incidents: Appendix 2 - Contact List

### **Legislation**

*Public Safety Preservation Act 1986*

*Ambulance Service Act 1991*

*Dangerous Goods Safety Management Act 2001 Dangerous Goods Safety Management Act 2001*

*Environmental Protection Act 1994*

*Explosives Act 1999*

*Transport Operations (Road Use Management - Dangerous Goods) Regulation 1998*

*Fire and Rescue Service Act 1990*

*Public Safety Preservation Act 1986*

*Police Powers and Responsibilities Act 2000*

*Public Health Act 2005*

*Public Health and Other Legislation Amendment Regulation 2007*

*Radiation Safety Act 1999*

Management

24 November 2010

Ms Frances Hayter  
Director  
Environment and Social Policy  
Queensland Resources Council  
Level 13  
33 Mary Street  
BRISBANE QLD 4000

Dear Frances

I refer to the work that the Department of Environment and Resource Management and the Queensland Resources Council have jointly undertaken with respect to the Fitzroy River Basin Model Conditions for Mine Water Management.

Enclosed are two documents - the agreed record of the workshop with the QRC, and the model conditions with amendments that DERM intends to make included in "track changes".

The following is a summary of the changes that have been made to the model conditions in reference to the particular issues identified in the Final Meeting Notes:

**(a) Notification timeframes**

Condition W12 has been amended as follows:

*The authority holder must notify the administering authority as soon as practicable (within no later than 6 hours of having commenced deliberately releasing mine affected water to the receiving environment from an authorised discharge point, and no later than 12 hours after any uncontrolled release from an authorised discharge point). Notification must include the submission of written advice to the administering authority of the following information:*

**(b) Dilutions and flow rates**

Condition W9 and Table 4 have been amended as a result of consultation with Dr Ian Ramsay of Environment and Natural Resource Science who attended the workshop.

The modified explanations to Table 4 and the amendments to Table 4 and condition W9 are believed by DERM to satisfactorily address the issues raised by QRC for the purposes of the model conditions. Condition W9 has been amended as follows:

The volume released through the release point(s) must not exceed the maximum allowable flow at any time determined by multiplying the recorded receiving water flow at the corresponding gauging station in Table 4 with the corresponding percentages for maximum release in Table 4.

As a matter of principle there can not be releases where there is no flow in a river. However the revised provisions give greater flexibility with respect to the calculation of the proportion of that flow that can be taken up by a mine discharge.

**(c) Suspended solid limits**

Table 2 has been amended to allow for the monitoring of turbidity as a measure of compliance where there is evidence of a correlation between turbidity and suspended solids.

The modified requirements of Table 2 are believed by DERM to satisfactorily address the issues raised by QRC for the purposes of the model conditions.

**(d) End of pipe water quality limits**

In essence the QRC position on this came down to a request that the model conditions provide for mixing zones in the rivers as a means of achieving water quality outcomes.

No changes have been made to the model conditions in relation to this matter. On review DERM considers that it is open to individual sites to make a case based on toxicity assessment at the end of pipe to deal with this issue.

**(e) Distinctions between different types of water releases**

QRC provided a detailed paper about ways in which it may be possible to define different types of water on mine sites – worked water and non-worked water. The paper sought to differentiate water that has been affected by mining activities from water that was unaffected.

This is a complex issue that DERM does not believe can be resolved by simple variations to the model conditions. DERM has gone some way towards dealing with part of this matter by including in the explanation to Table 1 some guidance about the exclusion as release points of sediment traps and dams that have been installed in accordance with the standards and requirements of an Erosion and Sediment Control Plan.

Revision of the way in which water on a mine site is classified and regulated should await the further review of the model conditions in the second half of 2011.

It is the responsibility of individual mines to be planning for the management of water in a timely fashion and with sufficient foresight to anticipate what impacts the accumulation and discharge of water may have. There are a range of measures that mines can take through amendments to environmental authorities and Transitional Environmental Programs that can be used to ensure that their operations are compliant with the *Environmental Protection Act 1994*.

DERM has recently approved a Transitional Environmental Program for Xstrata Coal's Rolleston Mine that goes further than the model conditions and under particular circumstances allows that mine to discharge water held on site thereby providing greater

capacity for the forthcoming wet season. DERM has had discussions with both Macarthur Coal and BMA about a similar approach for their mines. DERM will continue to respond to these issues in a timely and practical way.

I am aware that there is often a reluctance to go down the path of using a Transitional Environmental Program. It is nevertheless an effective lawful mechanism that is available to companies that may have difficult circumstances to manage, and wish to seek some dispensation in the way in which the normal environmental authority conditions apply.

With respect to these revised conditions taking effect, DERM intends to issue a 'letter of comfort' for the notification timeframes in order to minimise amendment application processes for this minor change. This will remain in effect until such time as a company makes an amendment application for other matters. The remaining changes to the model conditions will require evidence based applications and therefore will require an amendment application to be made in the normal way, that is it will be for each company to decide when/if they wish to have any changes made via an application for an amendment to their environmental authority.

Yours sincerely

  
Anne Lenz

**Meeting Notes - Final**  
**DERM / QRC Meeting**  
**Model Water Conditions (3 November 2010)**

**Discussion of Specific Issues**

**a) Notification timeframes**

This item related to model condition W12 which outlined the requirements for the initial notification timeframe and content requirements. Industry representatives indicated that the specified limit of 'no later than 6 hours of having commenced releasing mine affected water' was impractical due to the following reasons:

- Discharges often from overflowing rather than from turning on a valve (eg, from dam spillway or stormwater) – therefore the timing of the discharge not necessarily during business hours or immediately known.. There are also many types of minor 'passive' releases which are not necessarily located at authorised discharge points [as discussed in relation to item (e)].
- Size of some mine sites – some mines are extensive in area and can take best part of an hour or more to drive from one end to the other. In rainfall events, some roads may be inaccessible and therefore total time from commencement of discharge to notification time is likely to be more than 6 hours. In addition, there may be health and safety reasons during or just after severe storm events when personnel either cannot or should not access particular locations (eg, if there has been a landslip).
- When rainfall events commence overnight, this compromises ability to notify within 6 hours given the shortage of appropriately qualified or authorised staff to make a decision whether the condition is triggered or to prepare and issue correspondence.
- It is often impracticable to ascertain all of the content requirements for the notice immediately, for example, it may be difficult to ascertain estimated volume in poor lighting at night, it may be difficult to predict a release cessation timeframe for an overflow when it is uncertain whether a rainfall event will stop, ease or increase and impacts are often not immediately known. It has often not been the experience that DERM officers have been satisfied with initial 'rough estimates' and companies are concerned about appearing to give false and misleading information if they turn out to be incorrect in their forecasts of cessation time (due to uncertainty of forecast), volume or impacts. In addition, the term 'verification' in the condition appears to have led some DERM officers to take a stringent view of the content requirements.

Industry commented that the 6 hour requirement was perceived to be driven by a requirement that the Department receive notification about the discharge in order to 'meet the news cycle and brief the Minister'.

It was clarified that industry did not mean by this that they expected someone else to notify DERM first, but rather, that a 6 hour requirement is not practicable in terms of the content requirements.

Industry also emphasised that this is not a condition about notification of breaches or serious/material environmental harm, but rather, would normally apply to authorised releases. It is seen as unjustifiable to impose a more stringent period of notification for authorised releases, than in relation to the normal standard for notification of breaches or serious/material environmental harm.

#### **Solutions Proposed:**

- Industry representatives requested a 24 hour notification timeframe
- Another suggestion was to encourage a staged approach, including:
  - 1<sup>st</sup> stage :Notification within 6 hours, but without any supporting information [i.e. items for which information is known within 6 hours
  - 2<sup>nd</sup> stage: Completed notification within 24 hours complete with supporting information [i.e. items W12 a) through to f)]
- Another suggestion was for a 12 hours initial notification period.
- Leaving aside the question of timeframe, it was suggested that the potential for unnecessary over-notification could be minimised by more clearly defining the scope of which releases need to be notified and removing the term 'verification'. Although not included in the model conditions, the actual conditions received by many mines include an ambiguous definition of 'mine water' described as 'process water and contaminated water'. Potentially, this could include a greater range of types of water releases than intended [discussed in more detail at item (e) of the agenda].

**Action agreed** - there was agreement that DERM would give consideration to a 12 hour timeframe for reporting. The question about definitions was 'parked' until item (e) of the agenda was reached.

- It is noted that use of the word 'verification' in condition W12 has led some DERM officers and industry representatives to be particularly concerned about the extent of information required, particularly in relation to item (f). '*any details (including available data) regarding likely impacts on the receiving water (s).*'

#### **b) Dilutions and flow rates**

This issue is primarily about condition W9 of the model conditions: 'Contaminant release flow must not exceed 20% of receiving water flow rate.'

Ian Ramsay explained that, at the time the original model conditions were prepared, there was insufficient scientific data about what rate would be reasonable as a baseline (or in individual circumstances). DERM's intention had been for individual mines to negotiate appropriate flow rates, based on their particular circumstances. The intention to allow for variation in the 20% rate was supposed to be covered by the explanatory notes before Table 4.

Industry commented that this did not appear to have been the way that condition W9 was addressed in practice.

Industry representatives outlined their concern that they were retaining excessive volumes of good quality water given the restrictions on discharge dilutions with the receiving water flows, because the conditions prevent mines from releasing that water in a timely way during the current 'window of opportunity' before the wet season is fully underway, as natural flow rates are not sufficiently high yet. If the

industry cannot take the current 'window of opportunity', then day by day, the quality of the accumulating water is gradually deteriorating. By the time that natural flow rates are sufficiently high for releases to be permitted under the conditions, there will be a very large volume of water that will be released and the quality will be significantly worse.

It was confirmed that this is seen as an industry-wide issue and there were comments that nearly every mine is concerned about this issue.

Jon Womersley suggested that each mine should negotiate different flow rates on a case by case basis. One industry representative commented that they had been told that the 20% figure was a Cabinet decision and could not be varied, notwithstanding that the DERM officers involved said that they accepted that the scientific data provided would otherwise have been relevant.

Other industry representatives explained that negotiation of upstream natural flow rates is particularly difficult if a mine happens to be located at the top of a catchment..

**Action agreed** – there was agreement to reposition the explanatory notes in the condition (extended W9) to outline the case specific requirements when a 1:4 dilution cannot be achieved. It was proposed to relocate the paragraph within the existing explanatory note #4 '*under certain circumstances.....*'. There was discussion on how this would be reviewed on a case by case negotiation basis, although each and every submission would need to be supported by a characterisation of the quality of the water to be discharged, in particular the electrical conductivity values.

### **c) Suspended solid limits**

Industry representatives outlined concern over the requirements in Table 2 (Contaminant Release Limits) for suspended solids. It is understood that analytical tests for Suspended Solids have a longer laboratory turnaround time given the nature of the test and currently there is no reliable field based test to measure suspended solids.

Industry representatives concerned over inability to ensure compliance prior to discharge. This is because the contaminant release point is at 'end of pipe' and given the restrictions associated with turnaround time and field methods, there is no way to ensure prior to discharge that the suspended solids limit is met.

It was confirmed that this is seen as an industry-wide issue and there were comments that nearly every mine is concerned about this issue.

#### **Solutions proposed included:**

- DERM suggested looking at relationship between suspended solids results and turbidity and internally correlating results so that an empirical relationship is developed between two parameters for particular storages; and
- Introduce turbidity limit in place of suspended solids limit; and
- Measure suspended solids concentration, but not have this as part of the Contaminant Release Limits.

**Action agreed** – that DERM would give consideration to swapping turbidity for suspended solids, so that in table 2 'suspended solids' is 'n/a'. (Industry had no objection to continuing to monitor for suspended solids, provided that this is not a table 2 parameter preventing release.)

**d) End of pipe water quality limits**

Concern expressed over absence of recognised 'mixing zones' for discharges.

High EC water is being accumulated given restriction on mixing zones.

Preferred DERM position is:

- 'no mixing zone' for acute toxic contaminants;
- No amendment to the model conditions regarding a mixing zone, but that individual mines may still propose a case by case mixing zone, other than for acute toxic contaminants.

**Solutions proposed included:**

- Review case by case for sites that require mixing zone;
- DERM to provide guidance on toxicity assessment for end of pipe; and
- Consider use of diffusers.
- There was some suggestion by DERM that sites may create their own internal mixing zones, prior to 'end of pipe' discharge. Industry representatives responded that the low water quality parameter for EC means that some mines have had to mix salty water with fresh water on site to create adequate internal dilution, that is, an on-site mixing zone. A number of representatives commented that this leads to: (a) very large storages involving significant additional disturbance and the need for additional mining leases (infrastructure); and (b) high use of fresh water (such as overland flow), which could perhaps be more efficiently used for other purposes. DERM (Ed Donahue) noted the difficulties this is likely to create for water resource management, and that this is the reason for the current exemption for mining EAs under WRPs. There was some suggestion that this could compromise the new Water Resource Plan (due out soon) and also that ultimately applications to harvest fresh water could lead to forced relinquishment of water allocations (from pipelines). QRC suggested that this is an issue for DERM to resolve in a policy sense, between its environment arm and its water resources arm.

**Action agreed** – that DERM would give consideration to the issues raised and any possible solution.

**e) Distinctions between different types of water releases**

Industry provided some pre-prepared discussion notes on this matter (refer to these)

Industry concern over:

- confusion in industry and government over existing definitions, and that it would be preferred to have a demarcation with definitions of worked water and other waters;
- need to separate management of authorised releases versus waterflows managed under an erosion and sediment control plan
- too many structures being recognised as a contaminant release point within a mine's catchment. The majority of these releases could be managed via the Erosion and Sediment Control Plan if the water meets standards/outcomes

defined in the Erosion and Sediment Control Plan. The remaining discharge points need separate management that would be specified in Table 1.

- If each minor release (eg, sumps, levees, seepages, 'true' sediment dams) are required to be monitored under Table 2, the unintended consequence would be for mines to consolidate these items into larger storages, but it is better management to have smaller storages and releases.

**Action agreed** – that DERM would give consideration to the issues raised and propose a solution having:

- worked through QRC discussion notes and come back to QRC with response
- developed a ready reckoner of definitions to avoid confusion around terminology e.g. Passive versus Active, Mine Affected Water, Worked Water
- provided undertaking to provide communication to staff on the issue of 'over-regulating/ over-prescribing' too many discharge points on each and every structure. Instead that the intent of the authorised release points was only to cover controlled discharges, and it was accepted in discussion that this included spillways associated with controlled releases. In particular, the original practical intention was that 'true' sediment dams were intended to function under ESCPs, rather than under authorised discharge points and associated tables.
- Consideration should be given to the requirements for ESCPs, in particular, that sediment dams are properly located, cleaned out and properly maintained.

## **6. Arrangements for implementing changes to the Model Conditions**

DERM committed to providing response to QRC by Friday 11 November 2010. DERM indicated that it would advise QRC if an extra week was needed to prepare the response.

QRC invited DERM to continue to discuss any questions with QRC in the meantime, for example, if further information would be of assistance, or to discuss terminology and definitions.

## **7. Arrangements for review of Model Conditions post 2011 wet season**

DERM indicated that a review of the model conditions would be undertaken following the 2011 wet season once more monitoring data was available and a review of performance against conditions was completed. DERM indicated that it would develop and agree with QRC on a project plan (including terms of reference) for the conduct of that review, and that this would be done mid 2011.

DERM invited the industry to provide interim results in about March/April 2011.

## Final Model Water Conditions for Coal Mines in the Fitzroy Basin

### Note:

Explanatory notes are in green. DELETE prior to issue of EA.

Insertions required by applicants and or the administering authority are in blue. DELETE prior to issue.

### Contaminant Release

W1 Contaminants that will, or have the potential to cause environmental harm must not be released directly or indirectly to any waters except as permitted under the conditions of this environmental authority.

W2 The release of contaminants to waters must only occur from the release points specified in Table 1 and depicted in Figure 1 <this would be a plan or plans locating all monitoring (water quality and flow) and release points> attached to this environmental authority.

Table 1 (Contaminant Release Points, Sources and Receiving Waters)

### EXPLANATORY NOTES – Determining Contaminant Release Points:

Contaminant release points should be specified in Table 1 where they represent a potential source of water contaminated by the mining activity. Release points associated with erosion and sediment control structures that have been installed in accordance with the standards and requirements of an Erosion and Sediment Control Plan to manage run-off containing sediment only that is not likely to contain contaminants or have properties that would cause environmental harm, do not need to be separately identified in Table 1.

Release Point (RP)	Latitude or northing (GDA94)	Longitude or easting (GDA94)	Contaminant Source and Location	Monitoring Point	Receiving waters description
RP 1	XXXX	XXXX	e.g. Stormwater Dam Spillway Overflow	Dam Spillway	Wet Creek
RP 2	XXXX	XXXX	e.g. Dam overflow pipe	Sampling Tap on pipe where the pipe enters Sandy Creek	Sandy Creek

W3 The release of contaminants to waters must not exceed the release limits stated in Table 2 when measured at the monitoring points specified in Table 1 for each quality characteristic.

Table 2 (Contaminant Release Limits)

### EXPLANATORY NOTES – Setting interim release limits for EC:

Option (c) – To negotiate a higher value for end-of-pipe EC limits, it will be necessary to have sufficient background water quality data from historical flow events, ideally above each discharge point. This data should be used to demonstrate that there is sufficient "assimilative capacity" in receiving waters to receive mine discharges of the proposed higher EC levels and maximum flows specified in condition W9. In other words, the limits should be such that the predicted in-stream water quality downstream will always remain below 1000  $\mu\text{S}/\text{cm}$  EC (for example, using all historical data and assumptions of complete dilution). Consideration should also be given to the potential impact on any drinking water reservoirs immediately downstream of the discharge and the need to keep in-stream water quality below 750  $\mu\text{S}/\text{cm}$ .

Option (d) – To negotiate a stepped approach to achieve Option (b) or (c) it will be necessary to predict the likely downstream receiving water EC as a result of the proposed limits for each step proposed. It will be necessary to

**Department of Environment and Resource Management**  
 Conserving and managing Queensland's environment and natural resources

have sufficient background water quality data from historical flow events, ideally for each discharge point. The data should be used to demonstrate that there is sufficient assimilative capacity to receive mine discharges of the proposed higher EC levels and maximum flows specified in condition W9. The limits should be such that predicted the in-stream water quality downstream is not likely to result in environmental harm from high salinity impacts. Ideally, in-stream EC s should remain below 1000 µS/cm EC (for example, using all historical data and assumptions of complete dilution). Where in-stream EC is likely to be above 1000 µS/cm then a case should be put forward as to why this is required and comments about the likelihood and potential extent of impacts. Consideration should also be given to the potential impact on any drinking water reservoirs immediately downstream of the discharge and the need to keep in-stream water quality below 750 µS/cm.

Quality Characteristic	Interim Release Limits for all mines (limits to apply from the date of issue)	Future Release Limits from XXXX/XXXX (negotiated date) <i>Note: These future limits will apply from a yet to be negotiated date using alternative numbers that will be derived from the information gathered by any combination of the following: (1) the results of near field monitoring, (2) any studies or investigations carried out in accordance with recommendations 2 &amp; 3 of the Cumulative Impact Study on water quality in the Fitzroy River Basin. (3) any review of the QLD Water Quality Guidelines. (4) other relevant information  Note: This information should be available by the end of 2011 if not before and when it becomes available limits will be determined for each mine site based on the environmental values to be protected and in accordance with criteria below</i>	Monitoring frequency	Comment
Electrical conductivity (µS/cm)	Hierarchy for determining limits in priority order starting with (a): (a) for mines that do not release contaminants to waters - no conditions are required for release authorisation, then conditions W2, to W15 inclusive, W18, W19 and W43 can be deleted. (b) Current limit for those mine sites not under a TEP or 1500 EC (Maximum)* which ever is lower or (c) a negotiated higher limit value that does not result in the contaminant release exceeding a maximum 1000 EC in the receiving waters and where the mine site demonstrates to DERM that it is unreasonable and impractical to immediately comply with the 1500 EC limit in (b) above	Aquatic ecosystem protection (no drinking water value): An end-of-pipe limit to achieve in the range 0 to 1000 EC in the receiving waters. Table 3 (Release Contaminant Trigger Investigation Levels) Potential Contaminants

**EXPLANATORY NOTES – Table 3 Potential Contaminants:**

The quality characteristics listed below should be assessed on a site by site basis by each mine prior to finalisation of amendment applications. Based on this assessment, the quality characteristic should be either disregarded if below trigger levels; or included as priority contaminants in Table 3 if above trigger levels. Assessment should involve comparison of representative data from dams that have historically been discharged or likely to be discharged from contaminant release points in Table 1. Data may include historical results or sampling undertaken for this specific purpose. The intent here is that not all dams on site would need to be sampled but those that would make up the majority of water in dams with release points. It could also be demonstrated based on existing water quality information that the water source and relative water quality of some dam are the same, in which case such dams may not need to be sampled individually. For metals and metalloids, trigger levels apply if dissolved results exceed trigger levels. However, total (unfiltered) results for metals and metalloids can be used to disregard a characteristic for inclusion in Table 3. Terms include SMD – slightly moderately disturbed level of protection, guideline - refers ANZECC & ARMCANZ (2000), LOR – typical reporting for method stated. ICPMS/CV FIMS – analytical methods required to achieve LOR.

Quality Characteristic	Trigger Levels (µg/L)	Comment on Trigger Level
Boron	370	<i>For aquatic ecosystem protection, based on SMD guideline</i>
Cobalt	90	<i>For aquatic ecosystem protection, based on low reliability guideline</i>
Manganese	1900	<i>For aquatic ecosystem protection, based on SMD guideline</i>
Molybdenum	34	<i>For aquatic ecosystem protection, based on low reliability guideline</i>
Selenium	10	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>
Silver	1	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>
Uranium	1	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>
Vanadium	10	<i>For aquatic ecosystem protection, based on LOR for ICPMS</i>
Ammonia	900	<i>For aquatic ecosystem protection, based on SMD guideline</i>
Nitrate	1100	<i>For aquatic ecosystem protection, based on ambient Qld WQ Guidelines (2006) for TN</i>
Petroleum hydrocarbons (C6-C9)	20	
Petroleum hydrocarbons (C10-C36)	100	
Fluoride (total)	2000	<i>Protection of livestock and short term irrigation guideline</i>

**Note:**

1. All metals and metalloids must be measured as total (unfiltered) and dissolved (filtered). Trigger levels for metal/metalloids apply if dissolved results exceed trigger.
2. The list of quality characteristics required to be monitored as per Table 3 will be reviewed once the results of the monitoring data is gathered for the interim period until 31 December 2011 or an earlier date if the data is, or becomes, available and if it is determined that there is no need to monitor for certain individual quality characteristics these can be removed from Table 3.
3. SMD – slightly moderately disturbed level of protection, guideline refers ANZECC & ARMCANZ (2000).
4. LOR – typical reporting for method stated. ICPMS/CV FIMS – analytical method required to achieve LOR.

- W5** If quality characteristics of the release exceed any of the trigger levels specified in Table 3 during a release event, the environmental authority holder must compare the down stream results in the receiving waters to the trigger values specified in Table 3 and:
1. where the trigger values are not exceeded then no action is to be taken; or
  2. where the down stream results exceed the trigger values specified Table 3 for any quality characteristic, compare the results of the down stream site to the data from background monitoring sites and:
    - (a) if the result is less than the background monitoring site data, then no action is to be taken; or
    - (b) if the result is greater than the background monitoring site data, complete an investigation in accordance with the ANZECC & ARMCANZ 2000 methodology, into the potential for environmental harm and provide a written report to the administering authority in the next annual return, outlining:
      - (i) details of the investigations carried out; and
      - (ii) actions taken to prevent environmental harm.

*Note: Where an exceedance of a trigger level has occurred and is being investigated, in accordance with W5 2(b)(ii) of this condition, no further reporting is required for subsequent trigger events for that quality characteristic.*

- W6** If an exceedance in accordance with condition W5 2(b)(ii) is identified, the holder of the authority must notify the administering authority within 14 days of receiving the result.

#### Contaminant Release Events

- W7** The holder must install, operate and maintain a stream flow gauging station to determine and record stream flows at the locations upstream of each Release Point as specified in Table 4 for any receiving water into which a release occurs.
- W8** Notwithstanding any other condition of this environmental authority, the release of contaminants to waters must only take place during periods of natural flow events specified as minimum flow in Table 4 for the contaminant release point(s) specified in Table 1.

Table 4 (Contaminant Release during Flow Events)

**EXPLANATORY NOTES – Table 4**

**Gauging station description:**

The intent here is that every release point in Table 1 is associated with a gauging station that measures flow upstream of the discharge point. More than one discharge point may be associated with the same gauging station. The gauging station should be at a minimum distance from the discharge point such that water flow under trigger flow events will not significantly diminish by the time it reaches the discharge point. The location of the gauging station should ideally be such that it is not significantly affected by other upstream point source releases or times of discharge are limited to periods of "natural" flow.

Under certain circumstances it may be appropriate to have a downstream gauging station in addition to or in replace of an upstream gauging station. The location should ideally not be affected by the discharge (e.g. be measured off the main waterway). The need for this must be demonstrated on a case by case basis to show why an upstream gauging station is insufficient. This may be the case when mines are located in the upper parts of catchments or near the downstream confluence or a major waterway. Similarly, the gauging station should be at a distance from the discharge point such that water flow during triggered flow events will not significantly diminish between the discharge point and the measuring point (or the confluence with the creek being measured). For downstream flow triggers, some changes to calculation for flow triggers and maximum release flows would typically be required based on the relative sizes of the waterways involved.

**Minimum Flow Trigger:**

The intent for the minimum flow trigger is that the times of discharge are limited to times of natural flow events only (for ephemeral receiving waters). Ideally, the flow trigger should be chosen such that it represents, for example, an 80<sup>th</sup> percentile average daily flow (in m<sup>3</sup>/s) of a minimum ten year period. This or a similar approach should aim to eliminate discharges during "low flow" periods. The maximum discharge volume can then be calculated by dividing the upstream flow trigger by 4. The intent here is that a minimum dilution 1:4 is always maintained (20% of downstream flow). In some situations, this will not allow the mine to release sufficient quantities of water. Therefore, it is possible to propose more than one flow trigger. For example, a 40<sup>th</sup> percentile average daily flow trigger may also be used in addition to the initial 20<sup>th</sup> percentile flow trigger such that above the 40<sup>th</sup> percentile average daily flow trigger a higher release volume will be allowed during periods of higher in-stream flow (while still maintaining a 1:4 dilution ratio).

**Comment [r1]:** This number has caused a lot of confusion. The reality is that the number for most mines is close to high flow events which 80<sup>th</sup> percentile is more representative of. It is just an example anyway.

The expectation is that where flow gauging data is available, it is used to calculate flow triggers. Where gauging data is not available or is insufficient, flow triggers should be based on runoff/stream flow estimates using appropriate hydrological calculations or models and known catchment area, rainfall estimations etc.

Under certain circumstances, such as where a mine is in the upper part of the catchment, achieving a 1:4 dilution with receiving waters as described above may not allow the mine to discharge sufficient volumes. In such a case, a lower flow trigger must still be proposed but the discharge volume will also need to be linked to some downstream flow measure with sufficient dilution (ideally much greater than 1:4 or 20%). The minimum flow trigger would typically be based on a proportional catchment area between the local receiving catchment and the larger downstream catchment. In this case, an additional line is added in Table 4. Note that some flow must be measured in the local stream to permit release. The need for this must be demonstrated on a case by case basis and be supported by various flow calculations to demonstrate feasibility and show minimal environmental impacts.

Other special cases include discharges to creeks below water reservoirs or dams and these should be dealt with on a case by case basis to address the intent described above.

Receiving water description	Release Point	Gauging station description	Latitude or northing (GDA94)	Longitude or easting (GDA94)	Minimum Flow In Receiving Water Required for a Release Event	Percentage for maximum release	Flow recording Frequency
Wet Creek		Gauging station 1	XXXX	XXXX	The minimum flow trigger should limit discharge to periods outside of no or low natural flow.  The volume of flow can be determined by height of water or flow. The actual flow must be a quantifiable measure. Example: > or = 5 m <sup>3</sup> /sec	20% of flow in receiving water	Continuous (minimum daily)

**Department of Environment and Resource Management**  
 Conserving and managing Queensland's environment and natural resources

Downstream Larger Creek (Delete if not in upper catchment)*	Gauging station 2	XXXX	XXXX	To be included for upper catchment mines only. The minimum flow trigger should limit discharge to periods outside of no or low natural flow.  The volume of flow can be determined by height of water or flow. The actual flow must be a quantifiable measure.  Example: > or = 5 m <sup>3</sup> /sec	XX% of flow in receiving water (value will be typically much less than 20%)
---	----------------------	------	------	---	---

**\*Note: Flow must also be measured at the Wet Creek gauging station for release to be permitted based on this flow trigger.**

- W9** The volume released through the release point(s) must not exceed the maximum allowable flow at any time determined by multiplying the recorded receiving water flow at the corresponding gauging station in Table 4 with the corresponding percentages for maximum release in Table 4.
- W10** The daily quantity of contaminants released from each release point must be measured and recorded at the monitoring points in Table 1.
- W11** Releases to waters must be undertaken so as not to cause erosion of the bed and banks of the receiving waters, or cause a material build up of sediment in such waters.

**Notification of Release Event**

- W12** The authority holder must notify the administering authority as soon as practicable (within no later than 6 hours of having commenced deliberately releasing mine affected water to the receiving environment from an authorised discharge point, and no later than 12 hours after any uncontrolled release from an authorised discharge point). Notification must include the submission of written advice to the administering authority of the following information:
  - a) release commencement date/time;
  - b) expected release cessation date/time;
  - c) release point/s;
  - d) release volume (estimated);
  - e) receiving water/s including the natural flow rate; and
  - f) any details (including available data) regarding likely impacts on the receiving water(s).
